To support multi-hop connections, Kerberos provides both constrained and unconstrained delegation, but for most scenarios, constrained delegation is considered a security best practice. Constrained delegation allows a service to pass the security token of the user identity to a designated down-level service on a remote computer. For multi-tier applications, delegating a user identity from a middle tier application server to a backend database such as Analysis Services is a common requirement. For example, a tabular or multidimensional model that returns different data based on user identity would require identity delegation from a middle tier service to avoid having the user re-enter credentials, or getting security credentials some other way.

Constrained delegation requires additional configuration in Active Directory, where services on both the sending and receiving end of the request are explicitly authorized for delegation. Although there are configuration costs up front, once the service is configured, password updates are managed independently in Active Directory. You do not need to update stored account information in applications, as you would if using the stored credentials option described further on.

For more information about configuring Analysis Services for constrained delegation, see [Configure Analysis Services for Kerberos constrained delegation](#).

Note

Windows Server 2012 supports constrained delegation across domains. In contrast, configuring Kerberos constrained delegation in domains at lower functional levels, such as Windows Server 2008 or 2008 R2, require both client and server computers to be members of the same domain.

EffectiveUserName

EffectiveUserName is a connection string property used for passing identity information to Analysis Services. Power Pivot for SharePoint uses it to record user activity in the usage logs. Excel Services and PerformancePoint Services can use it to retrieve data used by workbooks or dashboards in SharePoint. It can also be used in custom applications or scripts that perform operations on an Analysis Services instance.

For more information about using EffectiveUserName in SharePoint, see [Use Analysis Services EffectiveUserName in SharePoint Server 2010](#).

Basic Authentication and Anonymous User

Basic authentication provides yet a fourth alternative for connecting to a backend server as a specific user. Using Basic authentication, the Windows user name and password are passed on the connection string, introducing additional wire encryption requirements to ensure sensitive information is protected while in transit. An important advantage to using Basic authentication is that the authentication request can cross domain boundaries.

For Anonymous authentication, you can set the anonymous user identity to a specific Windows user account (IUSR_GUEST by default) or an application pool identity. The anonymous user account will be used on the Analysis Services connection, and must have data access permissions on the Analysis Services instance. When you use this approach, only the user identity associated with the Anonymous account is used on the connection. If your application requires additional identity management, you will need to choose one of the other approaches, or supplement with an identity management solution that you provide.

Basic and Anonymous are available only when you configure Analysis Services for HTTP access, using IIS and the msmdpump.dll to establish the connection. For more information, see [Configure HTTP Access to Analysis Services on Internet Information Services \(IIS\) 8.0](#).

Stored Credentials

Most middle tier application services include functionality for storing a user name and password subsequently used to retrieve data from a down-level data store, such as Analysis Services or the SQL Server relational engine. As such, stored credentials provide a fifth alternative for retrieving data. Limitations with this approach include maintenance overhead associated with keeping user names and passwords up to date, and the use of a single identity on the connection. If your solution requires the identity of the original caller, then stored credentials would not be a viable alternative.

For more information about stored credentials, see [Create, Modify, and Delete Shared Data Sources \(SSRS\)](#) and [Use Excel Services with Secure Store Service in SharePoint Server 2013](#).

Configure Analysis Services for Kerberos constrained delegation

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

When configuring Analysis Services for Kerberos authentication, you are most likely interested in achieving one or both of the following outcomes: having Analysis Services impersonate a user identity when querying data; or having Analysis Services delegate a user identity to a down-level service. Each scenario calls for slightly different configuration requirements. Both scenarios require verification to ensure configuration was done properly.

Tip

Microsoft Kerberos Configuration Manager for SQL Server is a diagnostic tool that helps troubleshoot Kerberos related connectivity issues with SQL Server. For more information, see [Microsoft Kerberos Configuration Manager for SQL Server](#).

This topic contains the following sections:

- [Allow Analysis Services to impersonate a user identity](#)
- [Configure Analysis Services for trusted delegation](#)
- [Test for impersonated or delegated identity](#)

Note

Delegation is not required if the connection to Analysis Services is a single hop, or your solution uses stored credentials provided by SharePoint Secure Store Service or Reporting Services. If all connections are direct connections from Excel to an Analysis Services database, or based on stored credentials, you can use Kerberos (or NTLM) without having to configure constrained delegation.

Kerberos constrained delegation is required if the user identity has to flow over multiple computer connections (known as "double-hop"). When Analysis Services data access is contingent upon user identity, and the connection request is from a delegating service, use the checklist in the next section to ensure that Analysis

Services is able to impersonate the original caller. For more information about Analysis Services authentication flows, see [Microsoft BI Authentication and Identity Delegation](#).

As a security best practice, Microsoft always recommends constrained delegation over unconstrained delegation. Unconstrained delegation is a major security risk because it allows the service identity to impersonate another user on *any* downstream computer, service, or application (as opposed to just those services explicitly defined via constrained delegation).

Allow Analysis Services to impersonate a user identity

To allow up-level services such as Reporting Services, IIS, or SharePoint to impersonate a user identity on Analysis Services, you must configure Kerberos constrained delegation for those services. In this scenario, Analysis Services impersonates the current user using the identity provided by the delegating service, returning results based on role membership of that user identity.

[+] [Expand table](#)

Task	Description
Step 1: Verify that accounts are suitable for delegation	<p>Ensure that the accounts used to run the services have the correct properties in Active Directory. Service accounts in Active Directory must not be marked as sensitive accounts, or specifically excluded from delegation scenarios. For more information, see Understanding User Accounts.</p> <p>Note: Generally, all accounts and servers must belong to the same Active Directory domain or to trusted domains in the same forest. However, because Windows Server 2012 supports delegation across domain boundaries, you can configure Kerberos constrained delegation across a domain boundary if the domain functional level is Windows Server 2012. Another alternative is to configure Analysis Services for HTTP access and use IIS authentication methods on the client connection. For more information, see Configure HTTP Access to Analysis Services on Internet Information Services (IIS) 8.0.</p>
Step 2: Register the SPN	<p>Before setting up constrained delegation, you must register a Service Principal Name (SPN) for the Analysis Services instance. You will need the Analysis Services SPN when configuring Kerberos constrained delegation for middle tier services. See SPN registration for an Analysis Services instance for instructions.</p> <p>A Service Principal Name (SPN) specifies the unique identity of a service in a domain configured for Kerberos authentication. Client connections using</p>

Task	Description
	<p>integrated security often request an SPN as part of SSPI authentication. The request is forwarded to an Active Directory Domain Controller (DC), with the KDC granting a ticket if the SPN presented by the client has a matching SPN registration in Active Directory.</p>
Step 3: Configure constrained delegation	<p>After validating the accounts you want to use and registering SPNs for those accounts, your next step is to configure up-level services, such as IIS, Reporting Services, or SharePoint web services for constrained delegation, specifying the Analysis Services SPN as the specific service for which delegation is allowed.</p>
	<p>Services that run in SharePoint, such as Excel Services or Reporting Services in SharePoint mode, often host workbooks and reports that consume Analysis Services multidimensional or tabular data. Configuring constrained delegation for these services is a common configuration task, and necessary for supporting data refresh from Excel Services. The following links provide instructions for SharePoint services, as well as other services likely to present a downstream data connection request for Analysis Services data:</p> <p>Identity delegation for Excel Services (SharePoint Server 2010) or How to configure Excel Services in SharePoint Server 2010 for Kerberos authentication ↗</p> <p>Identity delegation for PerformancePoint Services (SharePoint Server 2010) ↗</p> <p>Identity delegation for SQL Server Reporting Services (SharePoint Server 2010)</p> <p>For IIS 7.0 see Configure Windows Authentication (IIS 7.0) ↗ or How to configure SQL Server 2008 Analysis Services and SQL Server 2005 Analysis Services to use Kerberos authentication ↗.</p> <p>When testing, connect from remote computers, under different identities, and query Analysis Services using the same applications as business users. You can use SQL Server Profiler to monitor the connection. You should see the user identity on the request. For more information, see Test for impersonated or delegated identity in this section.</p>

Configure Analysis Services for trusted delegation

Configuring Analysis Services for Kerberos constrained delegation allows the service to impersonate a client identity on a down-level service, such as the relational database engine, so that data can be queried as if the client was connected directly.

Delegation scenarios for Analysis Services are limited to tabular models configured for **DirectQuery** mode. This is the only scenario in which Analysis Services can pass

delegated credentials to another service. In all other scenarios, such as SharePoint scenarios mentioned in the previous section, Analysis Services is on the receiving end of the delegation chain. For more information about DirectQuery, see [DirectQuery Mode](#).

Note

A common misconception is that ROLAP storage, processing operations, or access to remote partitions somehow introduce requirements for constrained delegation. This is not the case. All of these operations are executed directly by the service account (also referred to as the processing account), on its own behalf. Delegation is not required for these operations in Analysis Services, given that permissions for such operations are granted directly to the service account (for example, granting db_datareader permissions on the relational database so that the service can process data). For more information about server operations and permissions, see [Configure Service Accounts \(Analysis Services\)](#).

This section explains how to set up Analysis Services for trusted delegation. After you complete this task, Analysis Services will be able to pass delegated credentials to SQL Server, in support of DirectQuery mode used in Tabular solutions.

Before you start:

- Verify that Analysis Services is started.
- Verify the SPN registered for Analysis Services is valid. For instructions, see [SPN registration for an Analysis Services instance](#)

When both prerequisites are satisfied, continue with the following steps. Note that you must be a domain administrator to set up constrained delegation.

1. In Active Directory Users and Computers, find the service account under which Analysis Services runs. Right-click the service account and choose **Properties**.

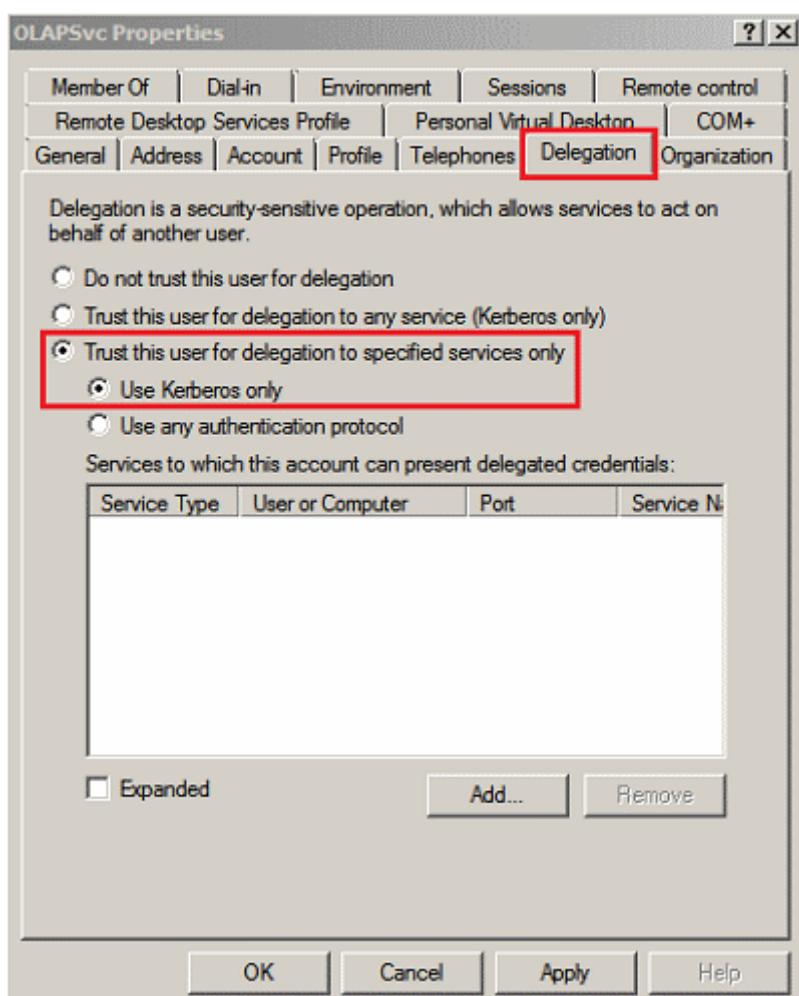

For illustrative purposes, the following screenshots use OlapSvc and SQLSvc to represent Analysis Services and SQL Server, respectively.

OlapSvc is the account that will be configured for constrained delegation to SQLSvc. When you complete this task, OlapSvc will have permission to pass delegated credentials on a service ticket to SQLSvc, impersonating the original caller when requesting data.

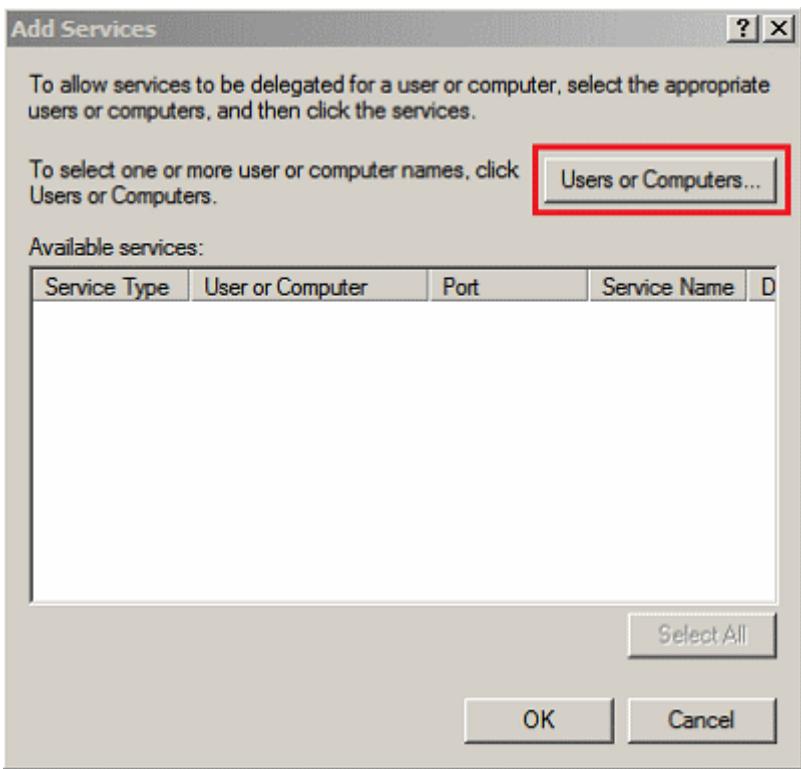

2. On the Delegation tab, select **Trust this user for delegation to specified services only**, followed by **Use Kerberos only**. Click **Add** to specify which service Analysis

Services is permitted to delegate credentials.

Delegation tab appears only when the user account (OlapSvc) is assigned to a service (Analysis Services), and the service has an SPN registered for it. SPN registration requires that the service is running.

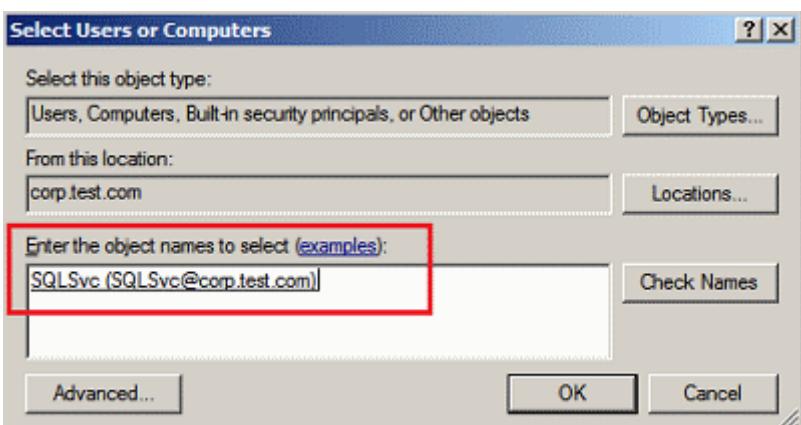

3. On the Add Services page, click **Users or Computers**.

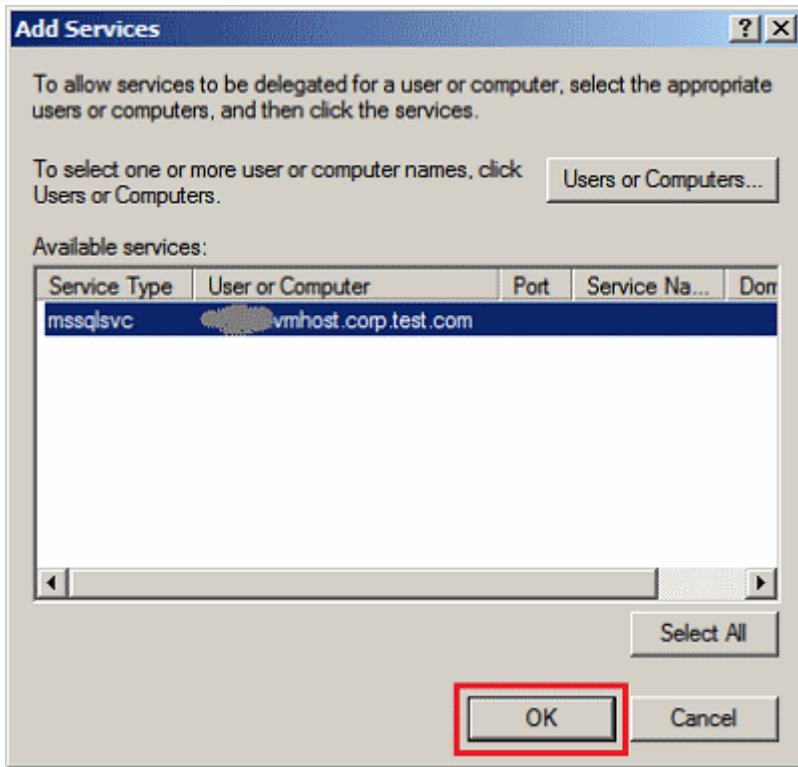

4. On the Select Users or Computer page, enter the account used to run the SQL Server instance providing data to Analysis Services tabular model databases. Click **OK** to accept the service account.

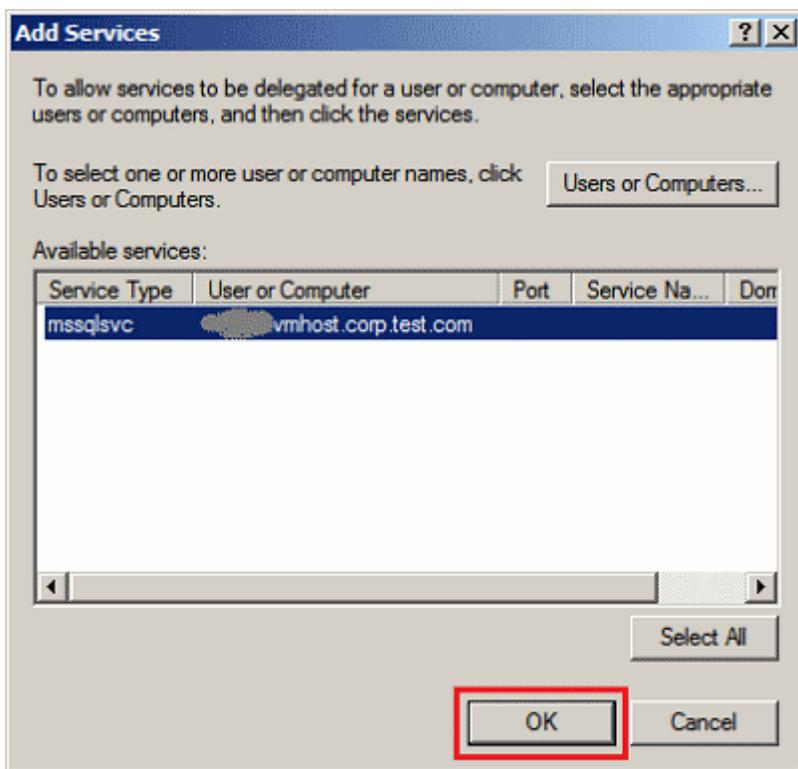

If you cannot select the account you want, verify that SQL Server is running and has an SPN registered for that account. For more information about SPNs for the database engine, see [Register a Service Principal Name for Kerberos Connections](#).

5. The SQL Server instance should now appear in Add Services. Any service also using that account will also appear in the list. Choose the SQL Server instance you want to use. Click **OK** to accept the instance.

6. The properties page of the Analysis Services service account should now look similar to the following screenshot. Click **OK** to save your changes.

7. Test for successful delegation by connecting from a remote client computer, under a different identity, and query the tabular model. You should see the user identity on the request in SQL Server Profiler.

Test for impersonated or delegated identity

Use SQL Server Profiler to monitor the identity of the user who is querying data.

1. Start **SQL Server Profiler** on the Analysis Services instance and then start a new trace.
2. In Events Selection, verify that **Audit Login** and **Audit Logout** are checked in the Security Audit section.
3. Connect to Analysis Services via an application service (such as SharePoint or Reporting Services) from a remote client computer. The Audit Login event will show the identity of the user connecting to Analysis Services.

Thorough testing will require the use of network monitoring tools that can capture Kerberos requests and responses on the network. The Network Monitor utility (netmon.exe), filtered for Kerberos, can be used for this task. For more information about using Netmon 3.4 and other tools for testing Kerberos authentication, see [Configuring Kerberos authentication: Core configuration \(SharePoint Server 2010\)](#).

SPN registration for an Analysis Services instance

Article • 01/18/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A Service Principal Name (SPN) uniquely identifies a service instance in an Active Directory domain when Kerberos is used to mutually authenticate client and service identities. An SPN is associated with the logon account under which the service instance runs.

For client applications connecting to Analysis Services via Kerberos authentication, the Analysis Services client libraries construct an SPN using the host name from the connection string and other well-known variables, such as the service class, that are fixed in any given release of Analysis Services.

For mutual authentication to occur, the SPNs constructed by the client must match a corresponding SPN object on an Active Directory Domain Controller (DC). This means that you might need to register multiple SPNs for a single Analysis Services instance to cover all of the ways in which a user might specify the host name on a connection string. For example, you probably need two SPNs to handle both the fully-qualified domain name (FQDN) of a server, as well as the short computer name. Correctly registering the Analysis Services SPN is essential for a successful connection. If the SPN is non-existent, malformed, or duplicated, the connection will fail.

SPN registration is a manual task performed by the Analysis Services administrator. Unlike the SQL Server database engine, Analysis Services never auto-registers its SPN at service startup. Manual registration is required when Analysis Services runs under the default virtual account, a domain user account, or a built-in account, including a per-service SID.

SPN registration is not required if the service runs under a predefined managed service account created by a domain administrator. Note that depending on the functional level of your domain, registering an SPN can require domain administrator permissions.

Tip

[Microsoft Kerberos Configuration Manager for SQL Server](#) is a diagnostic tool that helps troubleshoot Kerberos related connectivity issues with SQL Server. For

more information, see [Microsoft Kerberos Configuration Manager for SQL Server](#).

This topic contains the following sections:

[When SPN registration is required](#)

[SPN format for Analysis Services](#)

[SPN registration for a virtual account](#)

[SPN registration for a domain account](#)

[SPN registration for a built-in account](#)

[SPN registration for a named instance](#)

[SPN registration for an SSAS cluster](#)

[SPN registration for SSAS instances configured for HTTP access](#)

[SPN registration for SSAS instances listening on fixed ports](#)

When SPN registration is required

Any client connection that specifies "SSPI=Kerberos" on the connection string will introduce SPN registration requirements for an Analysis Services instance.

SPN registration is required under the following circumstances. For more detailed information, see [Configure Analysis Services for Kerberos constrained delegation](#).

- Identity delegation is necessary to flow the user identity from the client application or middle-tier service to Analysis Services. Identity delegation is typically used when per-user permissions or filters are defined on specific objects.

A common scenario involving identity delegation is configuring middle-tier services, such as Excel Services or Reporting Services, for constrained delegation for the purpose of impersonating a user identity when retrieving data in Analysis Services. To support this behavior, you must provide an Analysis Services SPN as the destination service when configuring Excel Services or Reporting Services for constrained delegation.

- Analysis Services delegates a user identity when retrieving data from a SQL Server relational database for tabular databases using DirectQuery mode. This is the only

scenario in which Analysis Services will delegate the user identity to another service.

SPN format for Analysis Services

Use **setspn** to register an SPN. On newer operating systems, **setspn** is installed as a system utility. For more information, see [SetSPN](#).

The following table describes each part of an Analysis Services SPN.

[] [Expand table](#)

Element	Description
Service class	MSOLAPSVc.3 identifies the service as an Analysis Services instance. The .3 is a reference to the version of the XMLA-over-TCP/IP protocol used in Analysis Services transmissions. It's unrelated to product release. As such, MSOLAPSVc.3 is the correct service class for SQL Server 2005, 2008, 2008 R2, 2012, and any future release of Analysis Services until the protocol itself is revised.
Host-name	<p>Identifies the computer on which the service is running. This can be a fully-qualified domain name or a NetBIOS name. You should register an SPN for both.</p> <p>When registering an SPN for the NetBIOS name of a server, be sure to use SetupSPN -s to check for duplicate registration. NetBIOS names aren't guaranteed to be unique in a forest, and having a duplicate SPN registration will cause the connection to fail.</p> <p>For Analysis Services load balanced clusters, the host name should be the virtual name assigned to the cluster.</p> <p>Never create an SPN using the IP address. Kerberos uses the DNS resolution capabilities of the domain. Specifying an IP address bypasses that capability.</p>
Port-number	Although the port number is part of SPN syntax, you never specify a port number when registering an Analysis Services SPN. The colon (:) character, typically used to provide a port number in standard SPN syntax, is used by Analysis Services to specify the instance name. For an Analysis Services instance, the port is assumed to be the default port (TCP 2383) or a port assigned by the SQL Server Browser service (TCP 2382).
Instance-name	<p>Analysis Services is a replicable service that can be installed multiple times on the same computer. Each instance is identified through its instance name.</p> <p>The instance name is prefixed with a colon (:) character. For example, given a host computer named SRV01 and a named instance of SSAS-Tabular, the SPN should be SRV01:SSAS-Tabular.</p>

Element	Description
	Note that the syntax for specifying a named Analysis Services instance differs from that used by other SQL Server instances. Other services uses a backslash (\) to append the instance name in an SPN.
Service-account	This is the startup account of the MSSQLServerOLAPService Windows service. It can be a Windows domain user account, virtual account, managed service account (MSA) or a built-in account such as a per-service SID, NetworkService, or LocalSystem. A Windows domain user account can be formatted as domain\user or user@domain.

SPN registration for a virtual account

Virtual accounts are the default account type for SQL Server services. The virtual account is **NT Service\MSOLAPService** for a default instance and **NT Service\MSOLAP\$<instance-name>** for a named instance.

As the name implies, these accounts do not exist in Active Directory. A virtual account exists only on the local computer. When connecting to external services, applications, or devices, the connection is made using the local machine account. For this reason, an SPN registration for Analysis Services running under a virtual account is actually an SPN registration for the machine account.

Example syntax for a default instance running as NT Service\MSOLAPService

This example shows **setspn** syntax for Analysis Services default instance running under the default virtual account. In this example, the computer host name is **AW-SRV01**. As noted, SPN registration must specify the *machine account* instead of the virtual account, **NT Service\MSOLAPService**.

```
Setspn -s MSOLAPSvc.3/AW-SRV01.AdventureWorks.com AW-SRV01
```

ⓘ Note

Remember to create two SPN registrations, one for the NetBIOS host name and a second for a fully-qualified domain name of the host. Different client applications use different host name conventions when connecting to Analysis Services. Having two SPN registrations ensures that both versions of the host name are accounted for.

Example syntax for a named instance running as NT Service\MSOLAP\$<instance-name>

This example shows **setspn** syntax for a named instance running under the default virtual account. In this example, the computer host name is **AW-SRV02**, and the instance name is **AW-FINANCE**. Again, it is the machine account that is specified for the SPN, rather than the virtual account **NT Service\MSOLAP\$<instance-name>**.

```
Setspn -s MSOLAPSvc.3/AW-SRV02.AdventureWorks.com:AW-FINANCE AW-SRV02
```

SPN registration for a domain account

Using a domain account to run an Analysis Services instance is a common practice.

For Analysis Services instances that run in a network or hardware load balanced cluster, a domain account is required, with each instance in the cluster running under the same domain account.

Example syntax for a default instance running as a domain user

This example shows **setspn** syntax for Analysis Services default instance running under a domain user account, **SSAS-Service**, in the AdventureWorks domain.

```
Setspn -s msolapsvc.3/AW-SRV01.Adventureworks.com AdventureWorks\SSAS-Service
```

Tip

Verify whether the SPN was created for the Analysis Services server by running

Setspn -L <domain account> or **Setspn -L <machinename>**, depending on how the SPN was registered. You should see **MSOLAPSVC.3/<hostname>** in the list.

SPN registration for a built-in account

Although this practice is not recommended, older Analysis Services installations are sometimes configured to run under built-in accounts like Network Service, Local Service, or Local System.

Example syntax for a default instance running under a built-in account

SPN registration for a service running under a built-in account or per-service SID is equivalent to the SPN syntax used for the virtual account. Instead of the account name, use the machine account:

```
Setspn -s MSOLAPSvc.3/AW-SRV01.AdventureWorks.com AW-SRV01
```

SPN registration for a named instance

By default, named instances of Analysis Services use dynamic port assignments that are detected by the SQL Server Browser service. You only need to create a NetBIOS and FQDN SPNs for the named instance to enable Kerberos connections.

Example syntax for a named instance running as a domain user

The following example shows the `setspn` syntax for Analysis Services named instance `AW-FINANCE` running under a domain user account, SSAS-Service, in the AdventureWorks domain. In this example, the computer host name is AW-SRV01.

```
FQDN SPN: Setspn -s MSOLAPSvc.3/AW-SRV01.AdventureWorks.com:AW-FINANCE  
AdventureWorks\SSAS-Service
```

```
NetBIOS SPN: Setspn -s MSOLAPSvc.3/AW-SRV01:AW-FINANCE AdventureWorks\SSAS-  
Service
```

Note

If you configured your named instance to listen on a fixed port, perform the following steps to use Kerberos connections from your client application:

1. Start the SQL Server Browser service.
2. If you're using a port number in your connection string, remove the port number, add the instance name, and let the application receive the port number through the SQL Server Browser service.

💡 Tip

Verify whether the SPN was created for the SQL named instance by running the `Setspn -L <domain account>` or `Setspn -L <machinename>` command, depending on how the SPN was registered.

Microsoft Kerberos Configuration Manager for SQL Server is a diagnostic tool that helps troubleshoot Kerberos related connectivity issues with SQL Server. This tool can help identify potential problems in SPNs and delegations and provide automated procedures to fix the identified issues. For more information, see [Microsoft Kerberos Configuration Manager for SQL Server](#).

SPN registration for an SSAS cluster

For Analysis Services failover clusters, the host name should be the virtual name assigned to the cluster. This is the SQL Server network name, specified during SQL Server Setup when you installed Analysis Services on top of an existing WSFC. You can find this name in Active Directory. You can also find it in **Failover Cluster Manager | Role | Resources** tab. The server name on the Resources tab is what should be used as the 'virtual name' in the SPN command.

SPN syntax for an Analysis Services cluster

```
Setspn -s msolapsvc.3/<virtualname.FQDN> <domain user account>
```

Recall that nodes in an Analysis Services cluster are required to use the default port (TCP 2383) and run under the same domain user account so that each node has the same SID. See [How to Cluster SQL Server Analysis Services](#) for more information.

SPN registration for SSAS instances configured for HTTP access

Depending on solution requirements, you might have configured Analysis Services for HTTP access. If your solution includes IIS as a middle tier component, and Kerberos authentication is a solution requirement, you might need to manually register an SPN for IIS. For more information, see "Configure the settings on the computer running IIS"

in [How to configure SQL Server 2008 Analysis Services and SQL Server 2005 Analysis Services to use Kerberos authentication](#).

In terms of SPN registration for the Analysis Services instance, there is no difference between an instance configured for TCP or HTTP. The connection to Analysis Services from IIS, using the MSMDPUMP ISAPI extension, is always TCP.

This means that you can use the instructions from previous sections for default or named instance to register the SPN. When specifying the host name, be sure to use the host name you specified in the msmdpump.ini file when you configured the service for HTTP access.

For more information about HTTP access, see [Configure HTTP Access to Analysis Services on Internet Information Services \(IIS\) 8.0](#).

SPN registration for SSAS instances listening on fixed ports

You can't specify a port number on an Analysis Services SPN registration. The Analysis Services SPN registration can only use instance name. If you installed Analysis Services as a default instance and configured it to listen on a non-default port, you can't connect to that instance using Kerberos. You must configure it to listen on the default port (TCP 2383) for enabling Kerberos connections to that instance. A default instance of Analysis Services listening on non-default port can only accept NTLM connections. For named instances, you need to start SQL Server Browser service and use instance names in your connection strings instead of port numbers.

An Analysis Services instance can only listen on a single port. Using multiple ports isn't supported. For more information about port configuration, see [Configure the Windows Firewall to Allow Analysis Services Access](#).

Configure HTTP Access to Analysis Services on IIS 8.0

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

This article explains how to set up an HTTP endpoint for accessing an Analysis Services instance. You can enable HTTP access by configuring MSMDPUMP.dll, an ISAPI extension that runs in Internet Information Services (IIS) and pumps data to and from client applications and an Analysis Services server. This approach provides an alternative means for connecting to Analysis Services when your BI solution calls for the following capabilities:

- Client access is over Internet or extranet connections, with restrictions on which ports can be enabled.
- Client connections are from non-trusted domains in the same network.
- Client application runs in a network environment that allows HTTP but not TCP/IP connections.
- Client applications cannot use the Analysis Services client libraries (for example, a Java application running on a UNIX server). If you cannot use the Analysis Services client libraries for data access, you can use SOAP and XML/A over a direct HTTP connection to an Analysis Services instance.
- Authentication methods other than Windows integrated security are required. Specifically, you can use Anonymous connections and Basic authentication when configuring Analysis Services for HTTP access. Digest, Forms, and ASP.NET authentication are not supported. A requirement of Basic authentication is one of the primary reasons for enabling HTTP access. To learn more, see [Microsoft BI Authentication and Identity Delegation](#).

Note

The client libraries required by client applications cannot connect to Analysis Services through proxy servers that require a username and password.

You can configure HTTP access for any supported version or edition of Analysis Services, running either tabular mode or multidimensional mode. Local cubes are an exception.

You cannot connect to a local cube via an HTTP endpoint.

Setting up HTTP access is a post-installation task. Analysis Services must be installed before you can configure it for HTTP access. As the Analysis Services administrator, you will need to grant permissions to Windows accounts before HTTP access is possible. Additionally, it is a best practice to validate your installation first, ensuring that it is fully operational before configuring the server any further. After HTTP access is configured, you can use both the HTTP endpoint and the regular network name of the server over TCP/IP. Setting up HTTP access does not invalidate other approaches for data access.

As you move forward with MSMDPUMP configuration, remember there are two connections to consider: client-to-IIS, IIS-to-SSAS. The instructions in this article are about IIS-to-SSAS. Your client application might require additional configuration before it can connect to IIS. Decisions such as whether to use SSL, or how to configure bindings, are out of scope for this article. See [Web Server \(IIS\)](#) for more information about IIS.

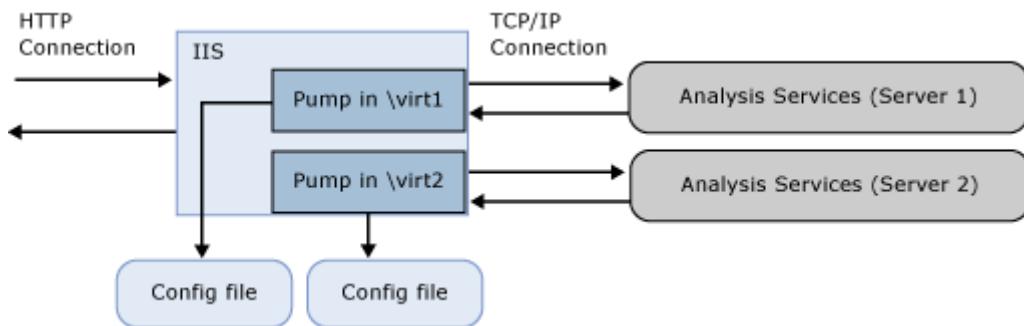

Overview

MSMDPUMP is an ISAPI extension that loads into IIS and provides redirection to a local or remote Analysis Services instance. By configuring this ISAPI extension, you create an HTTP endpoint to an Analysis Services instance.

You must create and configure one virtual directory for each HTTP endpoint. Each endpoint will need its own set of MSMDPUMP files, for each Analysis Services instance you want to connect to. A configuration file in this file set specifies the name of the Analysis Services instance used for each HTTP endpoint.

On IIS, MSMDPUMP connects to Analysis Services using the Analysis Services OLE DB provider over TCP/IP. Although client requests can originate outside of domain trust, both Analysis Services and IIS must be in the same domain or in trusted domains in order for the native connection to succeed.

When MSMDPUMP connects to Analysis Services, it does so under a Windows user identity. This account will either be the Anonymous account if you configured the virtual directory for anonymous connections, or a Windows user account. The account must have the appropriate data access rights on the Analysis Services server and database.

The following table lists additional considerations when you enable HTTP access for different scenarios.

[Expand table](#)

Scenario	Configuration
IIS and Analysis Services on the same computer	This is the simplest configuration because it allows you to use the default configuration (where the server name is localhost), the local Analysis Services OLE DB provider, and Windows integrated security with NTLM. Assuming that the client is also in the same domain, authentication is transparent to the user, with no additional work on your part.
IIS and Analysis Services on different computers	<p>For this topology, you must install the Analysis Services OLE DB provider on the web server. You must also edit the msmdpump.ini file to specify the location of Analysis Services instance on the remote computer.</p> <p>This topology adds a double-hop authentication step, where credentials must flow from the client to the web server, and on to the backend Analysis Services server. If you are using Windows credentials and NTLM, you will get an error because NTLM does not allow delegation of client credentials to a second server. The most common solution is to use Basic authentication with Secure Sockets Layer (SSL), but this will require users to provide a user name and password when accessing the MSMDPUMP virtual directory. A more straightforward approach might be to enable Kerberos and configure Analysis Services constrained delegation so that users can access Analysis Services in a transparent manner. See Configure Analysis Services for Kerberos constrained delegation for details.</p> <p>Consider which ports to unblock in Windows Firewall. You will need to unblock ports on both servers to allow access to the web application on IIS, and to Analysis Services on a remote server.</p>
Client connections are from a non-trusted domain or an extranet connection	Client connections from a non-trusted domain introduce further restrictions on authentication. By default, Analysis Services uses Windows integrated authentication, which requires users to be on the same domain as the server. If you have Extranet users who connect to IIS from outside the domain, those users will get a connection error if the server is configured to use the default settings.

Scenario	Configuration
	Workarounds include having Extranet users connect through a VPN using domain credentials. However, a better approach might be to enable Basic authentication and SSL on your IIS web site.

Prerequisites

The instructions in this article assume IIS is already configured and that Analysis Services is already installed. Windows Server 2012 ships with IIS 8.x as a server role that you can enable on the system.

Extra configuration in IIS 8.0

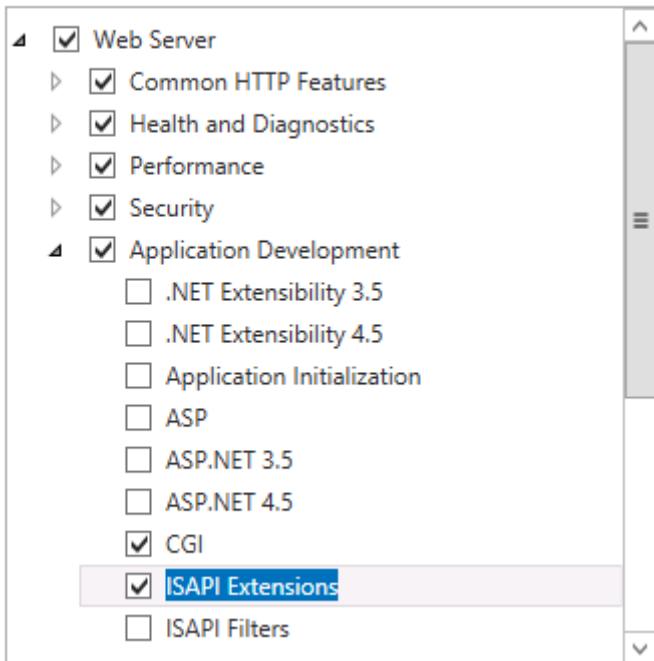

The default configuration of IIS 8.0 is missing components that are necessary for HTTP access to Analysis Services. These components, found in the **Security** and **Application Development** feature areas of the **Web Server (IIS)** role, include the following:

- **Security | Windows Authentication**, or **Basic Authentication**, and any other security features required for your data access scenario.
- **Application Development | CGI**
- **Application Development | ISAPI Extensions**

To verify or add these components, use **Server Manager | Manage | Add Roles and Features**. Step through the wizard until you get to **Server Roles**. Scroll down to find **Web Server (IIS)**.

1. Open **Web Server | Security** and choose the authentication methods.
2. Open **Web Server | Application Development** and choose **CGI** and **ISAPI Extensions**.

Role services

When IIS is on a remote server

A remote connection between IIS and Analysis Services requires that you install the Analysis Services OLE DB provider (MSOLAP) on the Windows server running IIS.

1. Go to the download page for [SQL Server 2014 Feature Pack ↗](#)
2. Click the red Download button.
3. Scroll down to find ENU\x64\SQL_AS_OLEDB.msi
4. Follow the instructions in the wizard to complete the installation.

ⓘ Note

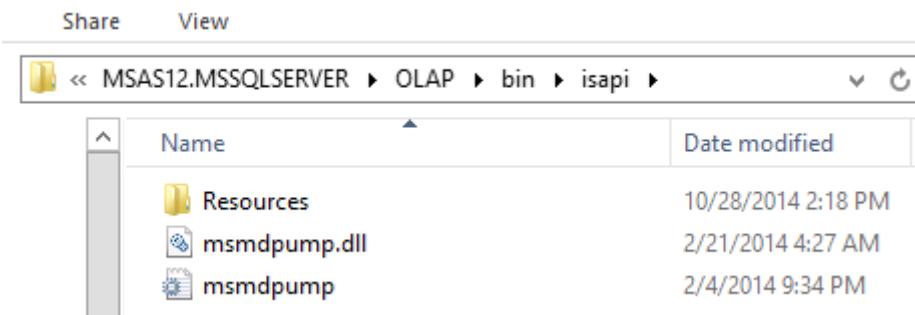

Remember to unblock the ports in Windows Firewall to allow client connections to a remote Analysis Services server. For more information, see [Configure the Windows Firewall to Allow Analysis Services Access](#).

Step 1: Copy the MSMDPUMP files to a folder on the Web server

Each HTTP endpoint that you create must have its own set of MSMDPUMP files. In this step, you copy the MSMDPUMP executable, configuration file, and resource folder from the Analysis Services program folders to a new virtual directory folder that you will create on the file system of the computer running IIS.

The drive must be formatted for the NTFS file system. The path to the folder that you create must not contain any spaces.

1. Copy the following files, found at <drive>:\Program Files\Microsoft SQL Server\<instance>\OLAP\bin\isapi: MSMDPUMP.DLL, MSMDPUMP.INI, and a Resources folder.

2. On the web server, create a new folder: <drive>:\inetpub\wwwroot\OLAP
3. Paste the files that you previously copied into this new folder.
4. Verify that the \inetpub\wwwroot\OLAP folder on your web server contains the following: MSMDPUMP.DLL, MSMDPUMP.INI, and a Resources folder. Your folder structure should look like this:
 - <drive>:\inetpub\wwwroot\OLAP\MSMDPUMP.dll
 - <drive>:\inetpub\wwwroot\OLAP\MSMDPUMP.ini
 - <drive>:\inetpub\wwwroot\OLAP\Resources

Note

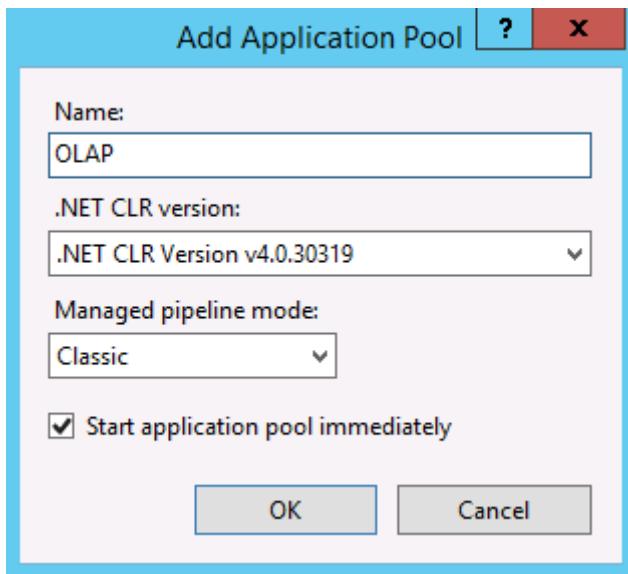

The IIS manager might not be able to connect to the Analysis Services in the current version if the Database is a backup from a previous one. This is caused by changes in the MSMDPUMP and should be solved by copying the msmdpump.dll file from the previous working version.

Step 2: Create an application pool and virtual directory in IIS

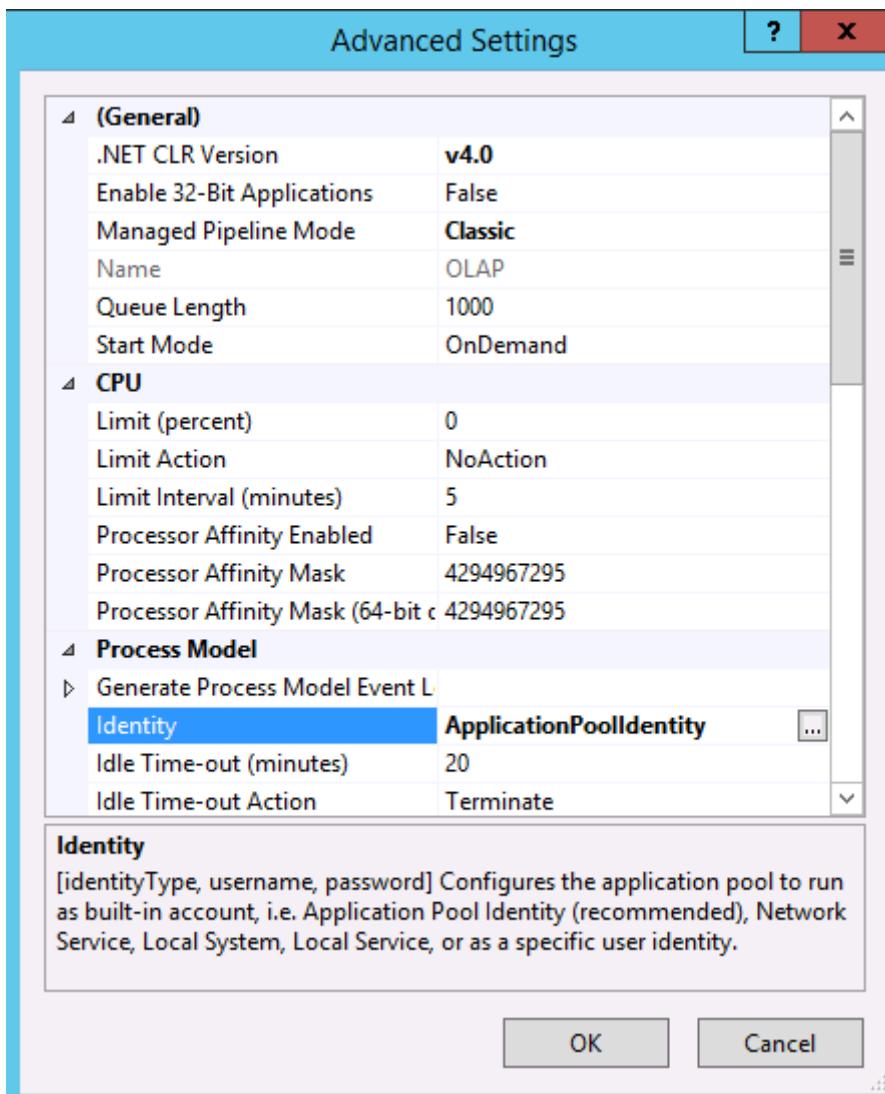

Next, create an application pool and an endpoint to the pump.

Create an application pool

1. Start IIS Manager.
2. Open the server folder, right-click **Application Pools** and then click **Add Application Pool**. Create an application pool named **OLAP**, using the .NET Framework, with Managed pipeline mode set to **Classic**.

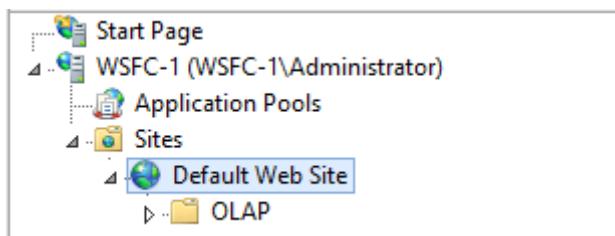

3. By default, IIS creates application pools using **ApplicationPoolIdentity** as the security identity, which is a valid choice for HTTP access to Analysis Services. If you have specific reasons for changing the identity, right-click **OLAP**, and then select **Advanced Settings**. Select **ApplicationPoolIdentity**. Click the **Change** button for this property to replace the built-in account with the custom account you want to use.

- By default, on a 64-bit operating system, IIS sets the **Enable 32-bit Applications** property to **false**. If you copied msmdpump.dll from a 64-bit installation of Analysis Services, this is the correct setting for the MSMDPUMP extension on a 64-bit IIS server. If you copied the MSMDPUMP binaries from a 32-bit installation, set it to **true**. Check this property now in **Advanced Settings** to ensure it is set correctly.

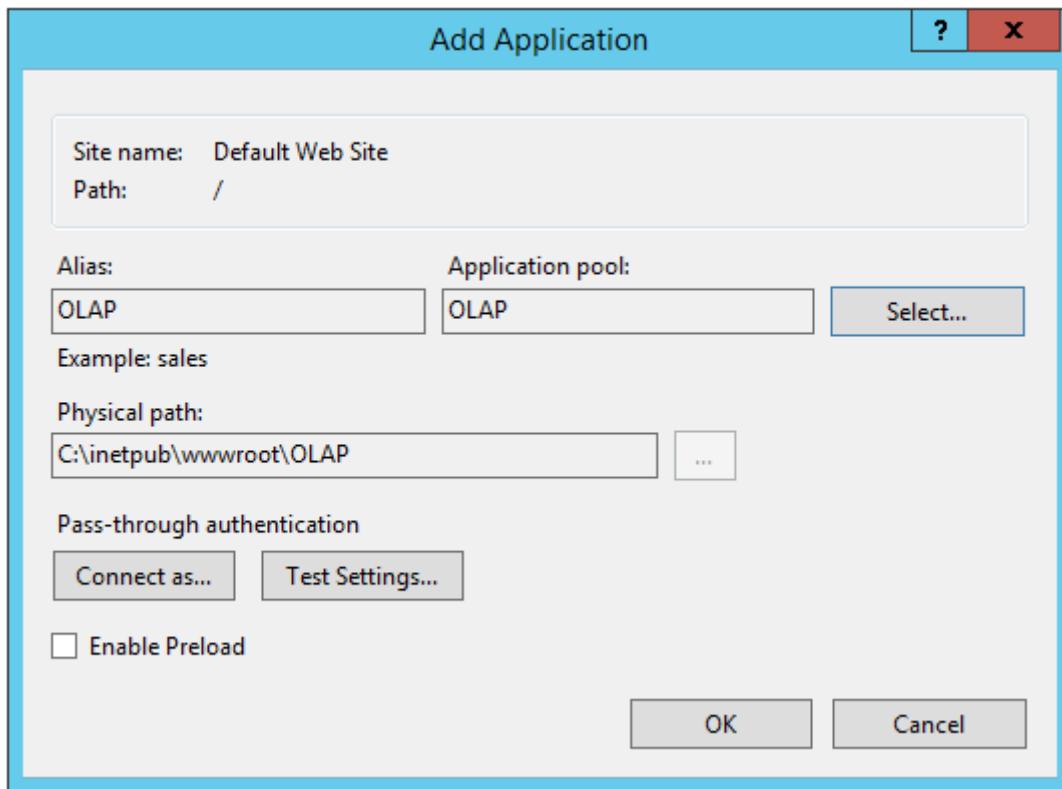

Create an application

- In IIS Manager, open **Sites**, open **Default Web Site**. You should see a folder named **Olap**. This is a reference to the OLAP folder you created under \inetpub\wwwroot.

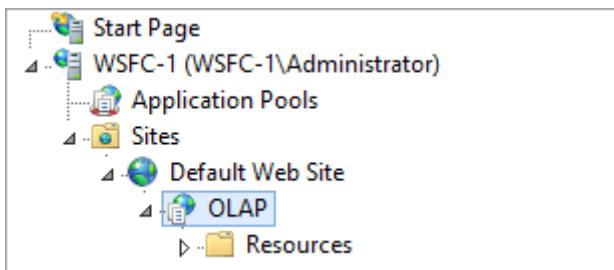

- Right-click the folder and choose **Convert to Application**.

3. In Add Application, enter **OLAP** for the alias. Click **Select** to choose the OLAP application pool. Physical Path should be set to C:\inetpub\wwwroot\OLAP

4. Click **OK**. Refresh the web site and notice that the OLAP folder is now an application under the default web site. The virtual path to the MSMDPUMP file is now established.

ⓘ Note

Previous versions of these instructions included steps for creating a virtual directory. That step is no longer necessary.

Step 3: Configure IIS authentication and add the extension

In this step, you further configure the SSAS virtual directory you just created. You will specify an authentication method and then add a script map. Supported authentication

methods for Analysis Services over HTTP include:

- Windows authentication (Kerberos or NTLM)
- Basic authentication
- Anonymous authentication

Windows authentication is considered the most secure, and leverages existing infrastructure for networks that use Active Directory. To use Windows authentication effectively, all browsers, client applications, and server applications must support it. This is the most secure and recommended mode, but it requires that IIS be able to access a Windows domain controller that can authenticate the identity of the user requesting a connection.

For topologies that put Analysis Services and IIS on different computers, you will need to address double-hop issues that arise when a user identity needs to be delegated to a second service on a remote machine, typically by enabling Analysis Services for Kerberos constrained delegation. For more information, see [Configure Analysis Services for Kerberos constrained delegation](#).

Basic authentication is used when you have Windows identities, but user connections are from non-trusted domains, prohibiting the use of delegated or impersonated connections. Basic authentication lets you specify a user identity and password on a connection string. Instead of using the security context of the current user, credentials on the connection string are used to connect to Analysis Services. Because Analysis Services supports only Windows authentication, any credentials passed to it must be a Windows user or group that is a member of the domain in which Analysis Services is hosted.

Anonymous authentication is often used during initial testing because its ease of configuration helps you to quickly validate HTTP connectivity to Analysis Services. In just a few steps, you can assign a unique user account as the identity, grant that account permissions in Analysis Services, use the account to verify data access in a client application, and then disable Anonymous authentication when testing is complete.

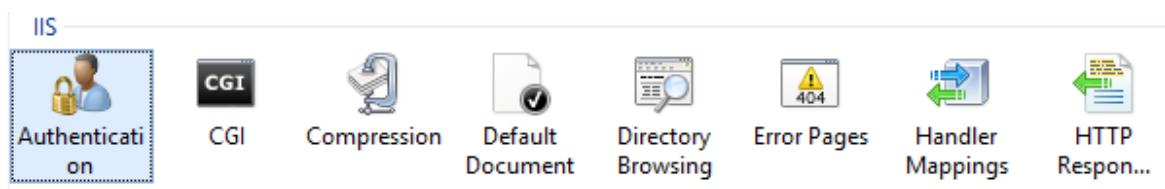

You can also use Anonymous authentication in a production environment if your users do not have Windows user accounts, but follow best practices by locking down permissions on the host system, as called out in this article: [Enable Anonymous Authentication \(IIS 7\)](#). Be sure that authentication is set on the virtual directory, and not on the parent web site, to further reduce the level of account access.

When Anonymous is enabled, any user connection to the HTTP endpoint is allowed to connect as the anonymous user. You won't be able to audit individual user connections,

nor use the user identity to select data from a model. As you can see, using Anonymous impacts everything from model design, to data refresh and access. However, if users do not have a Windows user login to start with, using the Anonymous account might be your only option.

Set the authentication type and add a script map

1. In IIS Manager, open **Sites**, open **Default Web Site**, and then select the OLAP virtual directory.
2. Double-click **Authentication** in the IIS section of the main page.

3. Enable **Windows Authentication** if you are using Windows integrated security.

A screenshot of the 'Authentication' settings page in IIS Manager. The table shows the following configuration:

Name	Status	Response Type
Anonymous Authentication	Disabled	
ASP.NET Impersonation	Disabled	
Basic Authentication	Disabled	HTTP 401 Challenge
Windows Authentication	Enabled	HTTP 401 Challenge

4. Alternatively, enable **Basic Authentication** if your client and server applications are in different domains. This mode requires the user to enter a user name and password. The user name and password are transmitted over the HTTP connection to IIS. IIS will try to impersonate the user using the provided credentials when connecting to MSMDPUMP, but the credentials will not be delegated to Analysis Services. Instead, you will need to pass a valid user name and password on a connection, as described in Step 6 in this document.

ⓘ Important

Please note that it is imperative for anyone building a system where the password is transmitted to have ways of securing the communication channel. IIS provides a set of tools that help you secure the channel. For more information, see [How to Set Up SSL on IIS 7](#).

5. Disable **Anonymous Authentication** if you are using Windows or Basic authentication. When Anonymous authentication is enabled, IIS will always use it first, even if other authentication methods are enabled.

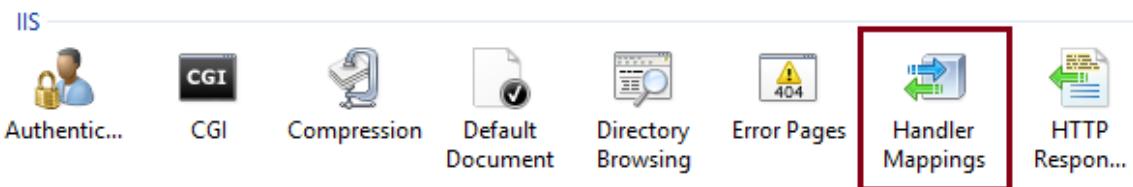

Under Anonymous authentication, the pump (msmdpump.dll) runs as the user account you established for anonymous user. There is no distinction between the user connecting to IIS and the user connecting to Analysis Services. By default, IIS uses the IUSR account, but you can change it to a domain user account that has network permissions. You'll need this capability if IIS and Analysis Services are on different computers.

For instructions on how to configure credentials for Anonymous authentication, see [Anonymous Authentication](#).

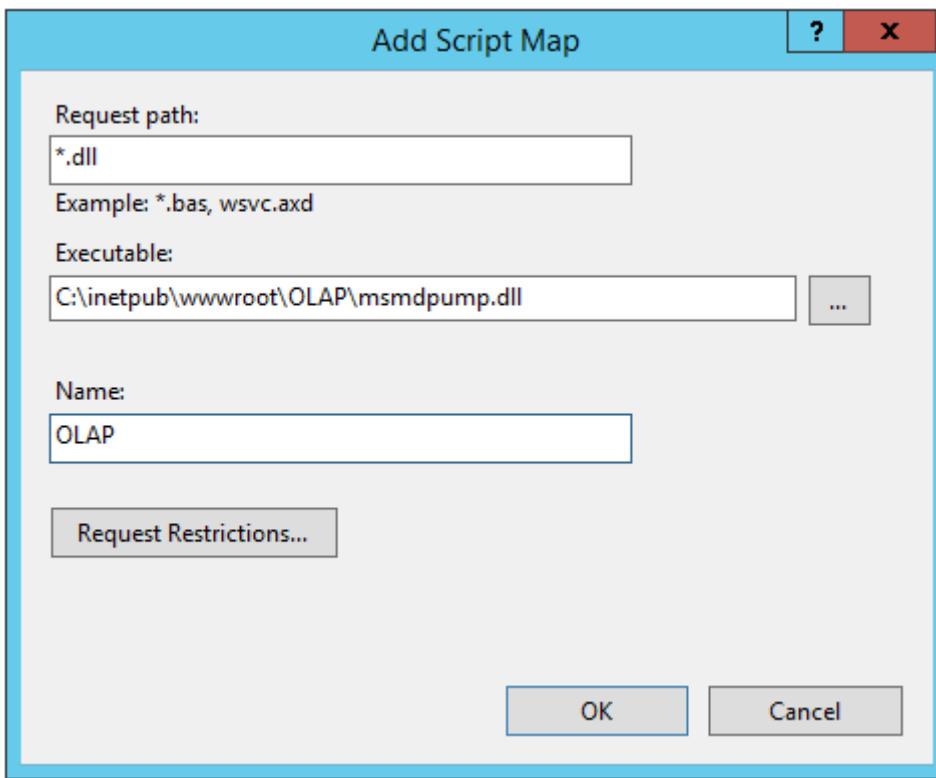

Important

Anonymous authentication is most likely found in an extremely controlled environment, where users are given or denied access by way of access control lists in the file system. For best practices, see [Enable Anonymous Authentication \(IIS 7\)](#).

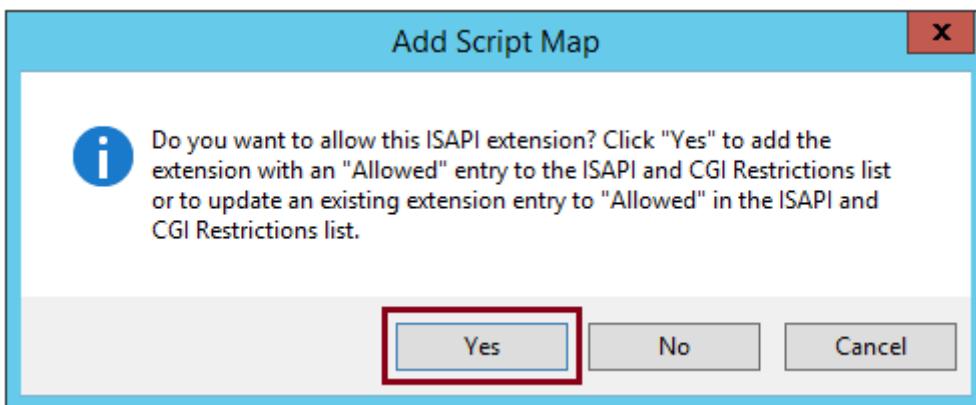

6. Click the **OLAP** virtual directory to open the main page. Double-click **Handler Mappings**.

7. Right-click anywhere on the page and then select **Add Script Map**. In the Add Script Map dialog box, specify ***.dll** as the request path, specify **c:\inetpub\wwwroot\OLAP\msmdpump.dll** as the executable, and type **OLAP** as the name. Keep all of the default restrictions associated with this script map.

8. When prompted to allow the ISAPI extension, click **Yes**.

Step 4: Edit the MSMDPUMP.INI file to set the target server

The MSMDPUMP.INI file specifies the Analysis Services instance that MSMDPUMP.DLL connects to. This instance can be local or remote, installed as the default or as a named instance.

Open the msmdpump.ini file located in folder C:\inetpub\wwwroot\OLAP and take a look at the contents of this file. It should look like the following:

```
<ConfigurationSettings>
<ServerName>localhost</ServerName>
<SessionTimeout>3600</SessionTimeout>
```

```
<ConnectionPoolSize>100</ConnectionPoolSize>
</ConfigurationSettings>
```

If the Analysis Services instance for which you are configuring HTTP access is located on the local computer and installed as a default instance, there is no reason to change this setting. Otherwise, you must specify the server name (for example, <ServerName>ADWRKS-SRV01</ServerName>). For a server that is installed as a named instance, be sure to append the instance name (for example, <ServerName>ADWRKS-SRV01\Tabular</ServerName>).

By default, Analysis Services listens on TCP/IP port 2383. If you installed Analysis Services as the default instance, you do not need to specify any port in <ServerName> because Analysis Services knows how to listen on port 2383 automatically. However, you do need to allow inbound connections to that port in Windows Firewall. For more information, see [Configure the Windows Firewall to Allow Analysis Services Access](#).

If you configured a named or default instance of Analysis Services to listen on a fixed port, you must add the port number to the server name (for example, <ServerName>AW-SRV01:55555</ServerName>) and you must allow inbound connections in Windows Firewall to that port.

Step 5: Grant data access permissions

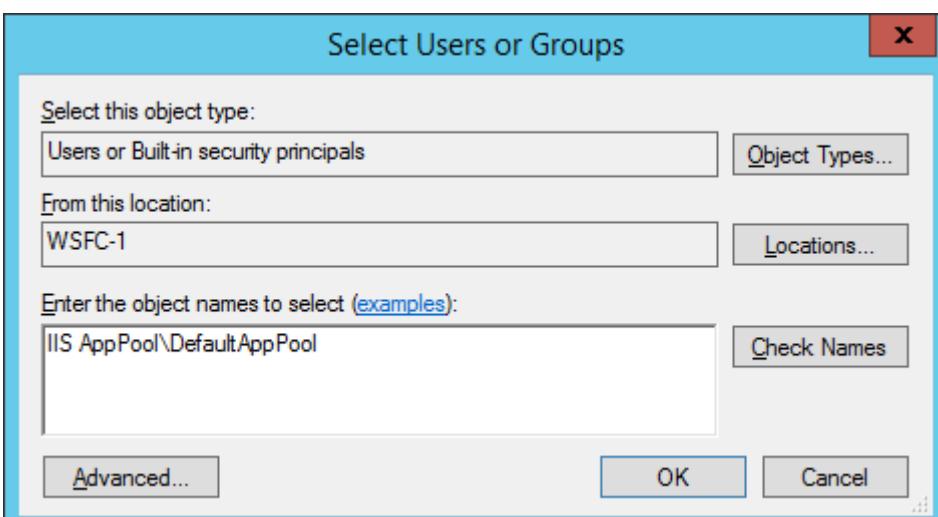

As previously noted, you will need to grant permissions on the Analysis Services instance. Each database object will have roles that provide a given level of permissions (read or read/write), and each role will have members consisting of Windows user identities.

To set permissions, you can use SQL Server Management Studio. Under the **Database | Roles** folder, you can create roles, specify database permissions, assign membership to Windows user or group accounts, and then grant read or write permissions on specific objects. Typically, **Read** permissions on a cube are sufficient for client connections that use, but do not update, model data.

Role assignment varies depending on how you configured authentication.

 [Expand table](#)

Authentication	Role assignment
Anonymous	Add to the Membership list the account specified in Edit Anonymous Authentication Credentials in IIS. For more information, see Anonymous

Authentication	Role assignment
Windows authentication	<p>Authentication ↴ , Add to the Membership list the Windows user or group accounts requesting Analysis Services data via impersonation or delegation.</p> <p>Assuming Kerberos constrained delegation is used, the only accounts that need permissions are the Windows user and group accounts requesting access. No permissions are necessary for the application pool identity.</p>
Basic authentication	<p>Add to the Membership list the Windows user or group accounts that will be passed on the connection string.</p> <p>In addition, if you are passing credentials via EffectiveUserName on the connection string, then the application pool identity must have administrator rights on the Analysis Services instance. In SSMS, right-click the instance Properties Security Add. Enter the application pool identity. If you used the built-in default identity, the account is specified as IIS AppPool\DefaultAppPool.</p> 

For more information about setting permissions, see [Authorizing access to objects and operations \(Analysis Services\)](#).

Step 6: Test your configuration

The connection string syntax for MSMDPUMP is the URL to the MSMDPUMP.dll file.

If the web application is listening on a fixed port, append the port number to the server name or IP address (for example, `http://my-web-srv01:8080/OLAP/msmdpump.dll` or

`http://123.456.789.012:8080/OLAP/msmdpump.dll`.

To quickly test the connection, you can open a connection using Internet Explorer, Microsoft Excel, or SQL Server Management Studio.

Troubleshoot connections using Internet Explorer

A connection request that terminates with this error might not give you much to go on: "Either a connection cannot be made to '<server name>', or Analysis Service is not running on the server".

To get a more informative error, do the following:

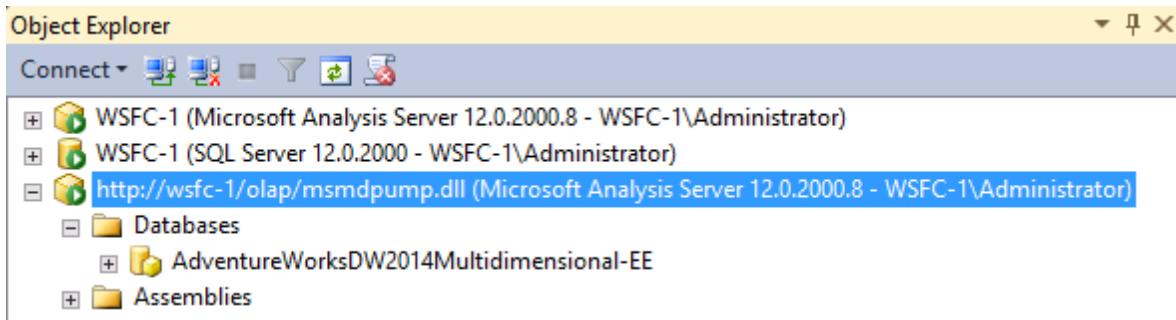

1. In Internet Explorer > Internet Options > Advanced, clear the checkbox for Show Friendly HTTP messages.
2. Retry the connection (for example, `http://my-web-srv01:8080/OLAP/msmdpump.dll`)

If you see an ERROR XML displayed in the browser window, you can eliminate MSMDPUMP as the potential cause and shift your focus to the certificate.

Test connections using SQL Server Management Studio

1. In Management Studio, in the Connect to Server dialog box, select **Analysis Services** as the server type. In Server name, enter the HTTP address of the msmdpump extension: `http://my-web-srv01/OLAP/msmdpump.dll`.

Object Explorer displays the HTTP connection:

2. Authentication must be Windows authentication, and the person using Management Studio must be an Analysis Services administrator. An administrator can grant further permissions to enable access by other users.

Test connections using Excel

1. On the Data tab in Excel, in Get External Data, click **From Other Sources**, and then choose **From Analysis Services** to start the Data Connection wizard.
2. In Server name, enter the HTTP address of the msmdpump extension: `http://my-web-srv01/OLAP/msmdpump.dll`.
3. For Log on credentials, choose **Use Windows Authentication** if you are using Windows integrated security or NTLM, or Anonymous user.

For Basic authentication, choose **Use the following User Name and Password**, and then specify the credentials used to sign on. The credentials you provide will be passed on the connection string to Analysis Services.

Test connections using AMO

You can test HTTP access programmatically using AMO, substituting the URL of the endpoint for the server name. For details, see [Forum Post \(How to sync SSAS 2008 R2 databases via HTTPS across domain/forest and firewall boundaries\)](#).

An example connection string illustrating the syntax for HTTP(S) access using Basic authentication:

```
Data Source=https://<servername>/olap/msmdpump.dll; Initial  
Catalog=AdventureWorksDW2012; Integrated Security=Basic; User ID=XXXX;  
Password=XXXXX;
```

For more information about setting up the connection programmatically, see [Establishing Secure Connections in ADOMD.NET](#).

As a final step, be sure to follow-up with more rigorous testing by using a client computer that runs in the network environment from which the connections will originate.

Disconnect users and sessions from Analysis Services

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

As an administrator, you may want to end user activity as part of workload management. You do this by canceling sessions and connections. Sessions can be formed automatically when a query is run (implicit), or named at the time of creation by the administrator (explicit). Connections to SQL Server Analysis Services are open conduits over which queries can be run. Azure Analysis Services and Power BI workspaces use sessions over HTTP. Both sessions and connections can be ended while they are active. For example, you may want to end processing for a session if the processing is taking too long, or if some doubt has arisen as to whether the command being executed was written correctly.

Ending Sessions and Connections

To manage sessions and connections, use Dynamic Management Views (DMVs) and XMLA:

1. In SQL Server Management Studio, connect to an Analysis Services instance.
2. Paste any one of the following DMV queries in an MDX query window to get a list of all sessions, connections, and commands that are currently executing:

```
Select * from $System.Discover_Sessions
```

```
Select * from $System.Discover_Connections
```

 (This query does not apply to Azure Analysis Services)

```
Select * from $System.Discover_Commands
```

3. Press F5 to execute the query.

The DMV query returns session and connection information in a tabular result set that is easier read and copy from.

Keep the query window open. In the next step, you will want to return to this page to copy the SPIDs of the session you want to disconnect.

To end a session, open a second XMLA query window.

1. Paste the following syntax into an MDX query window, replacing the ConnectionID, SessionID, or SPID placeholder with a valid value copied from the previous step.

```
<Cancel
xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">

<ConnectionID>111</ConnectionID>
<SessionID>222</SessionID>
<SPID>333</SPID>

<CancelAssociated>1</CancelAssociated>
</Cancel>
```

2. Press F5 to execute the cancel command.

Cancelling a SPID/SessionID will cancel any active commands running on the session corresponding to the SPID/SessionID. Cancelling a connection will identify the session associated with the connection, and cancel any active commands running on that session. In rare cases, a connection is not closed if the engine cannot track all sessions and SPIDs associated with the connection; for example, when multiple sessions are open in an HTTP scenario.

To learn more about the XMLA referenced in this topic, see [Execute Method \(XMLA\)](#) and [Cancel Element \(XMLA\)](#).

Analysis Services developer documentation

Article • 11/10/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

With Analysis Services, almost every object and workload is programmable, and often there is more than one approach to choose from. Options include writing managed code, script, or using open standards like XMLA and MSOLAP if your solution requirements preclude using the .NET framework.

What you can accomplish in code

Typical programming scenarios include server, database, and semantic model deployment, administration, data refresh and partition management, data access from custom applications, and external tools. Common to all these scenarios is a fixed architecture and object definition hierarchy, with well-understood operations that span data definition, processing, and query workloads.

Although objects and workloads are programmable, they're not extensible. Specifically, you cannot create custom data cartridges that retrieve data from unsupported data sources, customize or replace formula or storage engine behaviors, nor can you create new types of object metadata on a server, database, or model.

To further elaborate on the last point about creating new object types, while you can't create a new type of object, you can create calculated objects built from expressions or code at run time. Not everything in your model needs to be predefined and mapped to an existing data structure. Additionally, you can extend the schema via Annotations in AMO to pass object-specific information to your client application.

Choose a platform or approach to development

Analysis Services provides many ways to customize a solution through code, but most developers use the managed APIs or script.

- Managed APIs include [AMO](#) and [TOM](#) for data definition and administrative tasks, and [ADOMD.NET](#) for query support from client code. In SQL Server 2016 and later,

AMO is updated to use the new Tabular metadata for models created or upgraded to compatibility level 1200 and higher.

- Script can often achieve the same results as a program executable, with possibly less work.
 - You can write PowerShell script using Analysis Services PowerShell components that call AMO types directly. Within PowerShell, you can also create and execute ASSL/XMLA or TMSL (in JSON) script.
 - [TMSL](#) and [ASSL](#) are script languages that provide objects used in discover and execute operations. Which type of script you use depends on the underlying server, database, or model.
 - Tabular models or databases at compatibility level 1200 and higher use the Tabular Model Scripting Language (TMSL), which is in JSON.
 - Multidimensional models and Tabular models at compatibility levels 1050-1103 use Analysis Services Scripting Language (ASSL), which is the Analysis Services extension of the XMLA open standard.
 - You can generate ASSL or TMSL script in Management Studio. You can also use [View Code](#) in SQL Server Data Tools to view the model definition in ASSL or TMSL.
- While it's possible to build a solution based on the open standards of XMLA and MDX, it's quite rare to do so. There is no documentation other than XMLA and MDX reference to help you, and most community and forum support draws from experiences with .NET or native (MSOLAP) technologies.

Programming for Analysis Services

[Analysis Services Management Objects \(AMO\)](#) - Developer reference documentation for the managed provider, Analysis Services Management Objects (AMO), for data definition and administration, including processing.

[Tabular Object Model](#) - An extension of the AMO client library, created to support programming scenarios for tabular models created at compatibility level 1200 and higher.

[Tabular Model Definition Language \(TMDL\)](#) - An object model definition syntax for tabular data models at compatibility level 1200 or higher. Fully compatible with TOM. Text-based and optimized for human interaction and readability.

[Tabular Model Scripting Language \(TMSL\) Reference](#) - A JSON representation of Tabular models at compatibility level 1200 and higher. Object definitions are based on tabular metadata constructs like table, column, and relationship rather than multidimensional metadata that might be unfamiliar if you are new to Analysis Services data modeling in Tabular mode.

[Multidimensional model programming](#) - Describes the development tasks and approaches for integrating multidimensional model objects in a custom solution.

[ADOMD.NET](#) - Developer reference documentation for the managed provider, ADOMD.NET, used for programmatic data access and query workloads.

[XML for Analysis \(XMLA\) reference](#) - Describes XMLA concepts that can help you understand how XMLA contributes to your custom solution. It also describes the level of compliance with the XMLA 1.1 specification.

[Analysis Services Scripting Language \(ASSL for XMLA\)](#) - Describes the ASSL extensions to XMLA. ASSL provides a data definition and manipulation language for Analysis Services multidimensional models that supplements the XMLA specification.

[Analysis Services Schema Rowsets](#) - Describes the schema rowsets that provide information about server state, server operations, and database objects.

[Analysis Services PowerShell reference](#) - Documents the cmdlets used for administrative functions, plus the general-purpose **Invoke-ASCmd** cmdlet that accepts any script or query as input.

Analysis Services client libraries

Article • 04/11/2025

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Client libraries are necessary for client applications and tools to connect to Analysis Services. Microsoft client applications like Power BI Desktop, Excel, SQL Server Management Studio (SSMS), and Analysis Services projects extension for Visual Studio install all three client libraries and update them along with regular application updates. Custom client applications for Analysis Services may also require one or more of these client libraries to be installed. New versions of the client libraries are updated approximately monthly.

Important: Before getting the latest versions, be sure to see [Considerations and limitations](#).

Download the latest

Windows Installer

Expand table

Download	Version
MSOLAP (amd64)	17.0.17.20
MSOLAP (x86)	17.0.17.20
AMO	19.84.1.0
ADOMD	19.84.1.0

Note: The Windows Installer downloads for Analysis Services Management Objects (AMO/TOM) and ADOMD are no longer being updated and will not be available after Dec. 31st 2024. Applications relying on these Windows Installer downloads should be migrated to NuGet packages.

NuGet packages

Analysis Services Management Objects (AMO/TOM) and ADOMD client libraries are available as installable packages from [NuGet.org](#). It's strongly recommended you migrate to NuGet references instead of using the Windows Installer.

NuGet package assemblies AssemblyVersion follow semantic versioning: MAJOR.MINOR.PATCH. NuGet references load the expected version even if there's a different version in the GAC (resulting from MSI install). PATCH is incremented for each release. AMO and ADOMD versions are kept in-sync.

Starting July 2024, the AMO and ADOMD packages contain multi-runtime releases for all the supported target runtimes, both .NET FX as well as .NET Core; prior releases of the packages that only targeted a single runtime, either .NET FX or .NET Core, are available for backward compatibility, but are no longer updated.

Starting September 2022, AMO (AMO/TOM) and ADOMD .Net Core (version 19.48.0.0), HTTP-based communication with cloud services like Power BI and Azure Analysis Services is significantly improved. It's recommended you update to the latest version to take advantage of the performance improvements.

Starting Feb. 2021, [.NET Core](#) runtime support is available for the AMO and ADOMD client packages. There are, however, a few scenarios not-supported by the .NET Core versions. To learn more, see [considerations and limitations](#) later in this article.

AMO and ADOMD

[] [Expand table](#)

Package	Version
AMO	19.94.1.1
ADOMD	19.94.1.1

Note:

The new multi-runtime packages no longer have the ".retail.amd64" suffix in the package identity and are now simply called Microsoft.AnalysisServices and Microsoft.AnalysisServices.AdomdClient.

The older .NET Framework and .NET Core packages are still available in nuget.org for backward compatibility under the old identity with the ".retail.amd64" suffix for .NET Framework, and the ".NetCore.retail.amd64" suffix for .NET Core.

Minimum required versions

Transport Layer Security (TLS) protocol version 1.0/1.1 was [deprecated](#) in Microsoft Entra ID on June 30, 2021. TLS 1.2 or higher is now required. TLS 1.2 isn't supported in earlier versions of

the Analysis Services client libraries. Newer client library versions include support for TLS 1.2 and higher in addition to other important security enhancements.

To minimize risk and potential security vulnerabilities, beginning June 30, 2021, enhanced security in Azure Analysis Services and Power BI require the following or higher versions:

[+] Expand table

Client lib	File version	Version
MSOLAP	2018.151.61.21	15.1.61.21
AMO	15.1.61.21	19.12.3.0
ADOMD	15.1.61.21	19.12.3.0

Considerations and limitations

AMO and ADOMD

AdomdClient and AMO Packages of version 19.94.0.0 were released with a minor bug, and are replaced by version 19.94.1.1; if you are currently using version 19.94.0.0, please upgrade to a later version.

Beginning with version 19.94.1.1, the TMDL serialization options classes that are included in the AMO package, have a set of extension methods that simplify the usage of those classes, for more details please check the API reference documentation.

Beginning with version 19.94.1.1, there is an improvement in the error information that is raised in certain tabular authoring scenarios, like compatibility-violations and cross-reference errors. In the case of the compatibility-violation errors, the **CompatibilityViolationException** that is raised has more detailed messages and the properties related to the identifying the error, like **SupportedCompatibilityLevel**, **CompatibilityLevelRequest**, etc., are exposing the detailed information in more cases. In the case of deserialization of TMDL or TMSL that is resulted in an error in cross-reference resolution, a new designated exception is raised, **TmdlDeserializationWithReferenceErrorsException** and **JsonDeserializationWithReferenceErrorsException** respectively, that include a detailed error message that specify the properties that were failed to be resolved, as well as a property with more details about the resolution errors.

Starting with version 19.84.6, the support for .NET FX 4.5 and .NET Core 3.0 in the managed assemblies are no longer available. AS client-side assemblies are now released with support for .NET FX 4.7.2, as well as .NET 6.0 and .NET 8.0 only.

Beginning with version 19.82.0.0, AMO and ADOMD support Service Principal Profiles for authentication, as in the following connection string example. To learn more, see [Use service principal profiles to manage customer data in multitenant apps](#). Users can't connect to workspaces associated with a Premium Per-User license using Service Principal Profiles through the XMLA endpoint.

```
Data Source=powerbi://api.powerbi.com/v1.0/myorg/<WorkspaceName>;User ID=app:<service principal id>@<tenant id>;SPN Profile=<service-principal profile id>;Password=<service-principal's secret>
```

Beginning with version 19.67.0, connectivity objects like Microsoft.AnalysisServices.AdomdClient.AdomdConnection and Microsoft.AnalysisServices.Server, support a new **AccessToken** property that enables an improved way to pass external OAuth tokens to be used by the XMLA connectivity layer. To learn more, see [Connection string properties - User ID=...;Password=](#).

Beginning with version 19.42.0.4, ADOMD.NET and AMO/TOM use MSAL ([Microsoft.Identity.Client](#)) version 4.43.0 or higher instead of ADAL to authenticate users with Microsoft Entra ID when establishing a connection to cloud-based services like Power-BI and Azure Analysis Services. If your application or another component the application depends on is using MSAL, it may be necessary to update the application's binding redirect settings if there are conflicts between the versions of MSAL loaded by the components.

AMO and ADOMD .Net Core

Supported scenarios include connections to Azure Analysis Services, Power BI Premium, and SQL Server Analysis Services. TCP based connectivity is supported for Windows computers only.

Interactive login with Microsoft Entra ID is supported for Windows computers only. The .NET Core Desktop runtime is required.

Dependency in MSAL requires version 4.43.0 or higher.

Version 19.14.0 of the .Net Core client libraries introduced preview support for Self-Contained publishing (both in a published directory, and in single-file mode), in addition to support for consumption by .NET 5.0 projects. Several issues related to connectivity to SQL Server Analysis Services that were identified in the previous release have been fixed.

Version 19.12.7.2 of the .Net Core client libraries introduced support for SQL Server Analysis Services. Lower preview versions only supported Azure Analysis Services and Power BI semantic models.

AMO

Starting with version 19.84.6, the support for TMDL in AMO\TOM is considered as in General-Availability status, and there won't be any breaking changes in the API surface.

Version 19.12.3.0 of the AMO client library introduces a new enumeration, **Microsoft.AnalysisServices.DataType**. However, the previous enumeration, **Microsoft.AnalysisServices.Tabular.DataType** still exists. If your code references the previous enumeration as **DataType** in a code file with statements to both namespaces (**Microsoft.AnalysisServices**, **Microsoft.AnalysisServices.Tabular**), due to the ambiguity, you could get an error when compiling. To resolve the error, fully qualify the reference to the enumeration.

Version 19.61.1.4 of the AMO client library introduces a change in transaction rollback behavior of **Microsoft.AnalysisServices.Server**. In earlier versions, a call to [Server.RollbackTransaction\(\)](#) sends a request to the engine to roll back the transaction and then attempt to roll back local changes. Unlike earlier versions, in 19.61.1.4 and later, if local changes cannot be rolled back safely, tabular databases included in the transaction block any additional changes until they can be fully synced and the obsolete changes from the transaction that were rolled back are removed. An **InvalidOperationException** is raised when a change is made to the relevant tabular database. If your code is calling [Server.RollbackTransaction\(\)](#), it's recommended to follow that call with a full sync [\[Database.Refresh\(true\)\]](#) for any tabular database that is modified as part of the transaction.

Beginning with version 19.77.0, when cloning or copying a **MetadataObject** into another instance of a **MetadataObject** by using the Tabular Object Model (TOM), TOM returns null for properties that cross-reference objects outside of the **MetadataObject**'s direct tree of child objects. You must add the cloned **MetadataObject** instance to the semantic model so that cross references to objects outside of the **MetadataObject** tree can be resolved.

For example, when cloning a table with a partition that references a named expression in an **EntityPartitionSource**, the **ExpressionSource** property of the **EntityPartitionSource** returns null until the cloned table is added to the semantic model as in the code snippet below so that the cloned **ExpressionSource** reference can be resolved. The clone must be added to the model because the cross-referenced named expression is a member of the model's **Expressions** collection and not part of the table's tree of child objects.

```
Table tableClone = model.Tables[0].Clone();
anotherModel.Tables.Add(tableClone);
```

ADOMD

Beginning with ADOMD (both .NET Framework, and .NET Core) version 19.61.1.4, compression is fully available in the XMLA transport layer. Previous releases after version 19.55.3.1 implemented some partial support for compression. Reports about issues with those releases were received. Those issues were fixed as part of the 16.61.1.4 release. Be sure to upgrade to 19.61.1.4 or later if you're experiencing problems related to compression.

MSOLAP

Beginning with version 16.0.139.27, MSOLAP supports Service Principal Profiles for authentication, as in the following connection string example. To learn more, see [Use service principal profiles to manage customer data in multitenant apps.](#)

```
Data Source=powerbi://api.powerbi.com/v1.0/myorg/<WorkspaceName>;User ID=app:<service principal id>@<tenant id>;SPN Profile=<service-principal profile id>;Password=<service-principal's secret>
```

Beginning with version 16.0.134.22, MSOLAP supports silent Single Sign-On (SSO) using Web Account Manager (WAM), available on Windows 10 and higher as well as Window Server 2019 and higher. When a new HTTP connection is opened, MSOLAP obtains an access token as follows:

1. If token caching is enabled and a suitable token is available in the cache, MSOLAP uses the cached token.
2. If a suitable cached token is not available, MSOLAP attempts to obtain an access token silently through WAM.
3. If SSO using WAM failed, MSOLAP falls back to interactive authentication and pop-up the login window.

Users can bypass the silent SSO flow and immediately launch the interactive authentication experience by providing an 'empty' user id in the connection-string (User ID="").

Beginning with version 16.0.43.20, MSOLAP uses MSAL ([Microsoft.Identity.Client](#)) version 4.43.0 or higher instead of ADAL to authenticate users with Microsoft Entra ID when establishing a connection to cloud-based services like Power-BI and Azure Analysis Services. If your application or another component the application depends on is using MSAL, it may be necessary to update the application's binding redirect settings if there are conflicts between the versions of MSAL loaded by the components

A regression related to connections to cloud-based systems using Microsoft Entra ID was discovered in the 16.0.4.17 version of OLEDB (MSOLAP). It was fixed in the 16.0.20.201 version. Due to the nature of the issue, an installed 16.0.4.17 version, as well any other version prior to

16.0.20.201, cannot be corrected by upgrading the provider, even if setup is run in repair mode. It's recommended to completely uninstall the 16.0.4.17 [or other problematic] version and then install the 16.0.20.201 or later version.

In an earlier release, MSOLAP was updated to connect to cloud-based Analysis Services using the managed Microsoft Authentication Library (MSAL). Beginning with version 16.0.87.16, MSOLAP setup no longer installs the original native Azure Active Directory Authentication Library (ADAL) component.

Understanding client libraries

Analysis Services utilizes three client libraries. ADOMD.NET and Analysis Services Management Objects (AMO) are managed client libraries. And Analysis Services OLE DB Provider (MSOLAP DLL) is a native client library. Typically, all three are installed at the same time.

Microsoft client applications like Power BI Desktop and Excel install all three client libraries and update them when new versions are available. Depending on the version or frequency of updates, some client libraries may not be the latest versions required by Azure Analysis Services and Power BI. The same applies to custom applications or other interfaces such as AsCmd, TOM, ADOMD.NET. These applications require manually or programmatically installing the libraries. The client libraries for manual installation are included in SQL Server feature packs as distributable packages. However, these client libraries are tied to the SQL Server version and may not be the latest. Make sure you always install the latest, downloadable from this article.

Client library types

Analysis Services OLE DB Provider (MSOLAP)

Analysis Services OLE DB Provider (MSOLAP) is the native client library for Analysis Services database connections. It's used indirectly by both ADOMD.NET and AMO, delegating connection requests to the data provider. You can also call the OLE DB Provider directly from application code.

The Analysis Services OLE DB Provider is installed automatically by most tools and client applications used to access Analysis Services databases. It must be installed on computers used to access Analysis Services data.

OLE DB providers are often specified in connection strings. An Analysis Services connection string uses a different nomenclature to refer to the OLE DB Provider: MSOLAP.<version>.dll.

AMO

AMO is a managed client library used for server administration and data definition. It's installed and used by tools and client applications. For example, SQL Server Management Studio (SSMS) uses AMO to connect to Analysis Services. A connection using AMO is typically minimal, consisting of `"data source=\<servername>"`. After a connection is established, you use the API to work with database collections and major objects. Both Visual Studio and SSMS use AMO to connect to an Analysis Services instance.

ADOMD

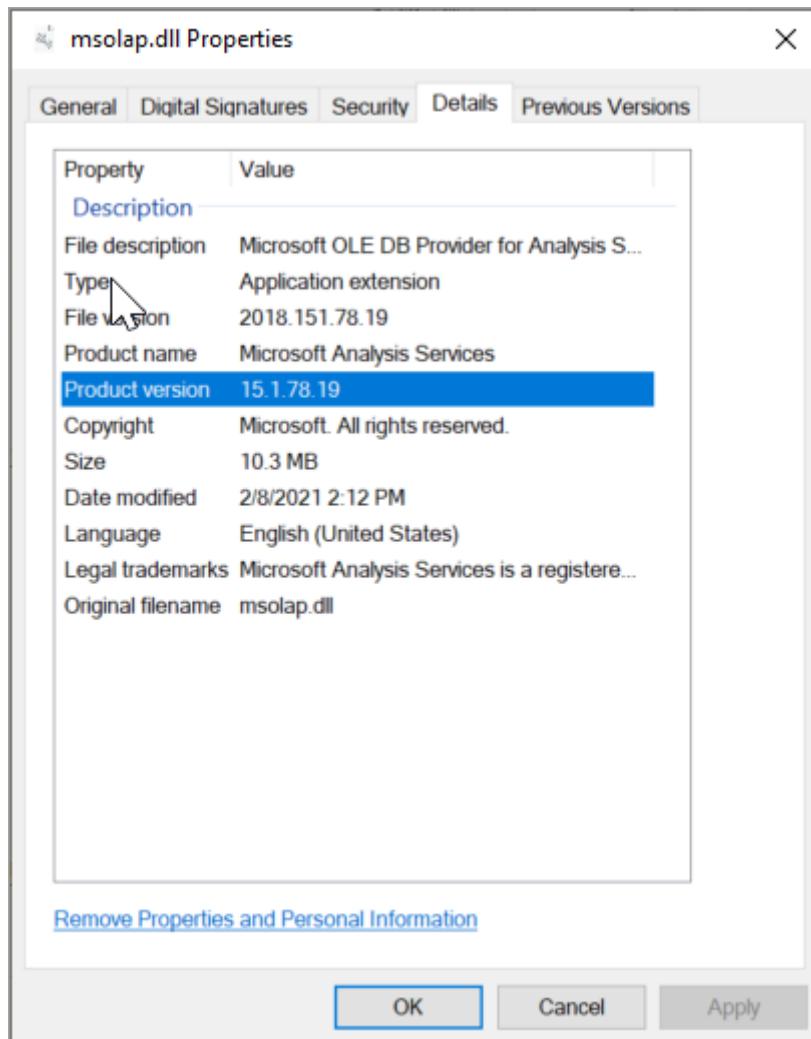

ADOMD.NET is a managed data client library used for querying Analysis Services data. It's installed and used by tools and client applications.

When connecting to a database, the connection string properties for all three libraries are similar. Almost any connection string you define for ADOMD.NET by using [Microsoft.AnalysisServices.AdomdClient.AdomdConnection.ConnectionString](#) also works for AMO and the Analysis Services OLE DB Provider (MSOLAP). To learn more, see [Connection string properties](#).

Check installed versions

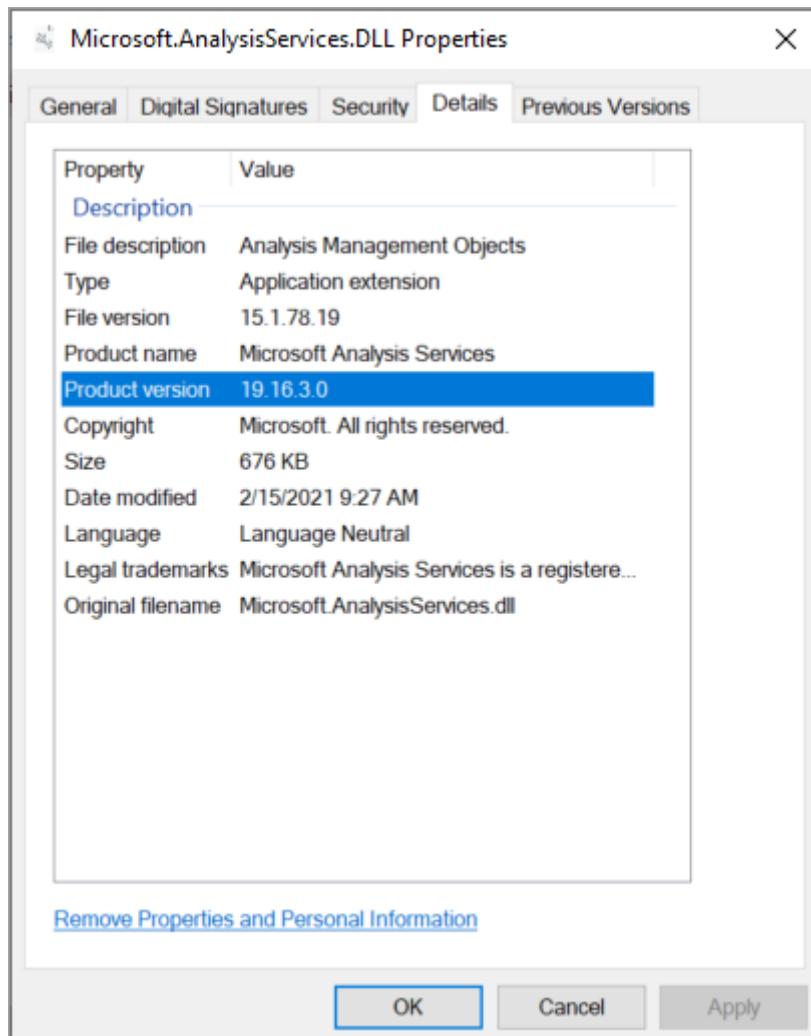

OLEDB (MSOLAP)

1. Go to `C:\Program Files\Microsoft Analysis Services\AS OLEDB\`. If you have more than one folder, choose the higher number.
2. Right-click **msolap.dll** > **Properties** > **Details**. Check the **Product version** property. Note: If the filename is msolap140.dll, it's older than latest version and should be upgraded.

AMO

1. Go to `C:\Windows\Microsoft.NET\assembly\GAC_MSIL\Microsoft.AnalysisServices\`. If you have more than one folder, choose the higher number.
2. Right-click **Microsoft.AnalysisServices** > Properties > Details.

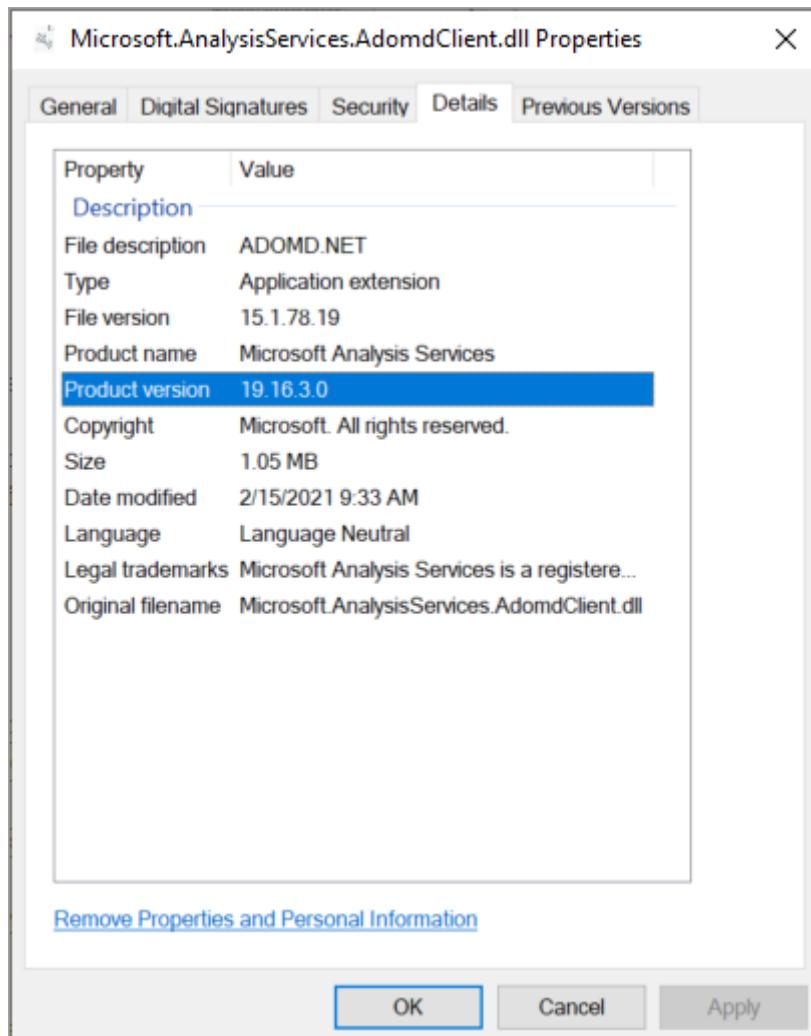

ADOMD

1. Go to

`C:\Windows\Microsoft.NET\assembly\GAC_MSIL\Microsoft.AnalysisServices.AdomdClient\`.

If you have more than one folder, choose the higher number.

2. Right-click **Microsoft.AnalysisServices.AdomdClient** > Properties > Details.

Manually update

Client libraries are typically installed and updated automatically along with tools and client applications that use them. However, in some cases client libraries may not be updated automatically and each must be manually updated. To update manually, download and run the Windows Installer (.msi) package for each client library.

To download and update

1. Click:

- [Download MSOLAP \(amd64\)](#) or [Download MSOLAP \(x86\)](#)
- [Download AMO](#)
- [Download ADOMD](#)

2. In **Downloads**, click a Windows Installer Package to run Setup.

3. In Setup, click **Next**.

4. Read the license agreement. If you agree, select **I accept the terms in the license agreement**, and then click **Next**.
5. Click, **Install**.
6. When completed, click **Finish**.

Tabular model programming for compatibility level 1200 and higher

Article • 04/10/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Beginning with compatibility level 1200, tabular metadata is used to describe model constructs, replacing historical multidimensional metadata as descriptors for tabular model objects. Metadata for tables, columns, and relationships are table, column, and relationship, rather than the multidimensional equivalents (dimension and attribute).

Important

Power BI Premium supports tabular models at the 1500 and higher compatibility level.

You can create new models at compatibility level 1200 or higher by using the `Microsoft.AnalysisServices.Tabular` APIs, the latest version of Visual Studio with Analysis Services projects, or by changing the **CompatibilityLevel** of an existing tabular model to upgrade it (also done in Visual Studio). Doing so binds the model to newer versions of the server, tools, and programming interfaces.

Upgrading an existing tabular solution is recommended but not required. Existing script and custom solutions that access or manage tabular models or databases can be used as-is. Azure Analysis Services supports compatibility level 1200 and higher only.

New tabular models require different code and script, summarized below.

Object model definitions as tabular metadata constructs

The Tabular Object Model for 1200 or higher models is exposed in JSON through the [Tabular Model Scripting Language](#) and through the AMO data definition language through a new namespace, [Microsoft.AnalysisServices.Tabular](#)

The [Tabular Model Definition Language \(TMDL\)](#) is text-based object model definition syntax for tabular data models at compatibility level 1200 or higher. It is fully compatible with the TOM.

Script for tabular models and databases

TMSL is a JSON scripting language for tabular models, with support for create, read, update, and delete operations. You can refresh data via TMSL and invoke database operations for attach, detach, backup, restore, and synchronize. AMO PowerShell accepts TMSL script as input.

See [Tabular Model Scripting Language \(TMSL\) Reference](#) and [Analysis Services PowerShell Reference](#) for more information.

Query languages

DAX and MDX are supported for all tabular models.

Expression language

Filters and expressions used to create calculated objects, including measures and KPIs, are formulated in DAX. See [DAX in tabular models](#).

Managed code for tabular models and databases

AMO includes a new namespace, Microsoft.AnalysisServices.Tabular, for working with models programmatically. See [Microsoft.AnalysisServices.Tabular Namespace](#) for more information.

Tabular model programming for compatibility levels 1050 and 1103

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Tabular models use relational constructs to model the Analysis Services data used by analytical and reporting applications. These models run on an Analysis Service instance that is configured for tabular mode, using an in-memory analytics engine for storage and fast table scans that aggregate and calculate data as it is requested.

If the requirements of your custom BI solution are best met by a tabular model database, you can use any of the Analysis Services client libraries and programming interfaces to integrate your application with tabular models on an Analysis Services instance. To query and calculate tabular model data, you can use either embedded MDX or DAX in your code.

For Tabular models created in earlier versions of Analysis Services, in particular models at compatibility levels 1050 through 1103, the objects you work with programmatically in AMO, ADOMD.NET, XMLA, or OLE DB are fundamentally the same for both tabular and multidimensional solutions. Specifically, the object metadata defined for multidimensional models is also used for tabular model compatibility levels 1050-1103.

Beginning with SQL Server 2016, Tabular models can be built or upgraded to the 1200 or higher compatibility level, which uses tabular metadata to define the model.

Metadata and programmability are fundamentally different at this level. See [Tabular Model Programming for Compatibility Level 1200 and higher](#) and [Upgrade Analysis Services](#) for more information.

Multidimensional Model Programming

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

SQL Server Analysis Services provides several APIs that you can use to program against an Analysis Services instance and the multidimensional databases that it makes available. This section describes the approaches available to developers who want to create custom applications using Analysis Services multidimensional solutions. You can use this information to choose the programming interface that best meets the requirements of a particular project. Analysis Services development projects can be based on managed or non-managed code that runs on a Windows platform, or other platforms that support HTTP access.

Multidimensional Model Assemblies Management

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Microsoft SQL Server SQL Server Analysis Services supplies lots of intrinsic functions for use with the Multidimensional Expressions (MDX) and Data Mining Extensions (DMX) languages, designed to accomplish everything from standard statistical calculations to traversing members in a hierarchy. But, as with any other complex and robust product, there is always the need to extend the functionality of such a product further.

Therefore, SQL Server Analysis Services lets you add assemblies to an SQL Server Analysis Services instance or database. Assemblies let you create external, user-defined functions using any common language runtime (CLR) language, such as Microsoft Visual Basic .NET or Microsoft Visual C#. You can also use Component Object Model (COM) Automation languages such as Microsoft Visual Basic or Microsoft Visual C++.

Important

COM assemblies might pose a security risk. Due to this risk and other considerations, COM assemblies were deprecated in SQL Server 2008 Analysis Services (SSAS). COM assemblies might not be supported in future releases.

Assemblies let you extend the business functionality of MDX and DMX. You build the functionality that you want into a library, such as a dynamic link library (DLL) and add the library as an assembly to an instance of SQL Server Analysis Services or to an SQL Server Analysis Services database. The public methods in the library are then exposed as user-defined functions to MDX and DMX expressions, procedures, calculations, actions, and client applications.

An assembly with new procedures and functions can be added to the server. You can use assemblies to enhance or add custom functionality that is not provided by the server. By using assemblies, you can add new functions to Multidimensional Expressions (MDX), Data Mining Extensions (DMX), or stored procedures. Assemblies are loaded from the location where the custom application is run, and a copy of the assembly binary file is saved along with the database data in the server. When an assembly is removed, the copied assembly is also removed from the server.

Assemblies can be of two different types: COM and CLR. CLR assemblies are assemblies developed in .NET Framework programming languages such as C#, Visual Basic .NET, managed C++. COM assemblies are COM libraries that must be registered in the server.

Assemblies can be added to [Server](#) or [Database](#) objects. Server assemblies can be called by any user connected to the server or any object in the server. Database assemblies can be called only by [Database](#) objects or users connected to the database.

A simple [Assembly](#) object is composed of basic information (Name and Id), file collection, and security specifications.

The file collection refers to the loaded assembly files and their corresponding debugging (.pdb) files, if the debugging files were loaded with the assembly files. Assembly files are loaded from the location where the application defined the files to, and a copy is saved in the server along with the data. The copy of the assembly file is used to load the assembly every time the service is started.

Security specifications include the permission set and the impersonation used to run the assembly.

Calling User-Defined Functions

Calling a user-defined function in an assembly is performed just like calling an intrinsic function, except that you must use a fully qualified name. For example, a user-defined function that returns a type expected by MDX is included in an MDX query, as shown in the following example:

```
Select MyAssembly.MyClass.MyStoredProcedure(a, b, c) on 0 from Sales
```

User-defined functions can also be called using the CALL keyword. You must use the CALL keyword for user-defined functions which return recordsets or void values, and you cannot use the CALL keyword if the user-defined function depends on an object in the context of the MDX or DMX statement or script, such as the current cube or data mining model. A common use for a function called outside an MDX or DMX query is to use the AMO object model to perform administrative functions. If, for example, you wanted to use the function `MyVoidProcedure(a, b, c)` in an MDX statement, the following syntax would be employed:

```
Call MyAssembly.MyClass.MyVoidProcedure(a, b, c)
```

Assemblies simplify database development by enabling common code to be developed once and stored in a single location. Client software developers can create libraries of functions for SQL Server Analysis Services and distribute them with their applications.

Assemblies and user-defined functions can duplicate the function names of the SQL Server Analysis Services function library or of other assemblies. As long as you call the user-defined function by using its fully qualified name, SQL Server Analysis Services will use the correct procedure. For security purposes, and to eliminate the chance of calling a duplicate name in a different class library, SQL Server Analysis Services requires that you use only fully qualified names for stored procedures.

To call a user-defined function from a specific CLR assembly, the user-defined function is preceded by the assembly name, full class name, and procedure name, as demonstrated here:

AssemblyName.FullClassName.ProcedureName(Argument1, Argument2, ...)

For backward compatibility with earlier versions of SQL Server Analysis Services, the following syntax is also acceptable:

AssemblyName!FullClassName!ProcedureName(Argument1, Argument2, ...)

If a COM library supports multiple interfaces, the interface ID can also be used to resolve the procedure name, as demonstrated here:

AssemblyName!InterfaceID!ProcedureName(Argument1, Argument2, ...)

Security

Security for assemblies is based on the .NET Framework security model, which is a code-access security model. .NET Framework supports a code-access security mechanism that assumes that the runtime can host both fully trusted and partially trusted code. The resources that are protected by .NET Framework code access security are typically wrapped by managed code which demands the corresponding permission before enabling access to the resource. The demand for the permission is satisfied only if all the callers (at the assembly level) in the call stack have the corresponding resource permission.

For assemblies, permission for execution is passed with the **PermissionSet** property on the **Assembly** object. The permissions that managed code receives are determined by

the security policy in effect. There are already three levels of policy in effect in a non-SQL Server Analysis Services hosted environment: enterprise, computer and user. The effective list of permissions that code receives is determined by the intersection of the permissions obtained by these three levels.

SQL Server Analysis Services supplies a host-level security policy level to the CLR while hosting it; this policy is an additional policy level below the three policy levels that are always in effect. This policy is set for every application domain that is created by SQL Server Analysis Services.

The SQL Server Analysis Services host-level policy is a combination of SQL Server Analysis Services fixed policy for system assemblies and user-specified policy for user assemblies. The user-specified piece of the SQL Server Analysis Services host policy is based on the assembly owner specifying one of three permission buckets for each assembly:

 Expand table

Permission Setting	Description
Safe	Provides internal computation permission. This permission bucket does not assign permissions to access any of the protected resources in the .NET Framework. This is the default permission bucket for an assembly if none is specified with the PermissionSet property.
ExternalAccess	Provides the same access as the Safe setting, with the additional ability to access external system resources. This permission bucket does not offer security guarantees (although it is possible to secure this scenario), but it does give reliability guarantees.
Unsafe	Provides no restrictions. No security or reliability guarantees can be made for managed code running under this permission set. Any permission, even a custom permission included by the administrator, is granted to code running at this level of trust.

When CLR is hosted by SQL Server Analysis Services, the stack-walk based permission check stops at the boundary with native SQL Server Analysis Services code. Any managed code in SQL Server Analysis Services assemblies always falls into one of the three permission categories listed earlier.

COM (or unmanaged) assembly routines do not support the CLR security model.

Impersonation

Whenever managed code accesses any resource outside SQL Server Analysis Services, SQL Server Analysis Services follows the rules associated with the **ImpersonationMode** property setting of the assembly to make sure that the access occurs in an appropriate Windows security context. Because assemblies using the **Safe** permission setting cannot access resources outside SQL Server Analysis Services, these rules are applicable only for assemblies using the **ExternalAccess** and **Unsafe** permission settings.

- If the current execution context corresponds to Windows Authenticated login and is the same as the context of the original caller (that is, there is no EXECUTE AS in the middle), SQL Server Analysis Services will impersonate the Windows Authenticated login before accessing the resource.
- If there is an intermediate EXECUTE AS that changed the context from that of the original caller), the attempt to access external resource will fail.

The **ImpersonationMode** property can be set to **ImpersonateCurrentUser** or **ImpersonateAnonymous**. The default setting, **ImpersonateCurrentUser**, runs an assembly under the current user's network login account. If the **ImpersonateAnonymous** setting is used, the execution context corresponds to the Windows login user account `IUSER_servername` on the server. This is the Internet guest account, which has limited privileges on the server. An assembly running in this context can only access limited resources on the local server.

Application Domains

SQL Server Analysis Services does not expose application domains directly. Because of a set of assemblies running in the same application domain, application domains can discover each other at execution time by using the **System.Reflection** namespace in the .NET Framework or in some other way, and can call into them in late-bound manner. Such calls will be subject to the permission checks used by SQL Server Analysis Services authorization-based security.

You should not rely on finding assemblies in the same application domain, because the application domain boundary and the assemblies that go into each domain are defined by the implementation.

Developing with Analysis Services Scripting Language (ASSL)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Analysis Services Scripting Language (ASSL) is an extension to XMLA that adds an object definition language and command language for creating and managing Analysis Services structures directly on the server. You can use ASSL in custom application to communicate with Analysis Services over the XMLA protocol. ASSL is made up of two parts:

- A Data Definition Language (DDL), or object definition language, defines and describes an instance of SQL Server Analysis Services, as well as the databases and database objects that the instance contains.
- A command language that sends action commands, such as **Create**, **Alter**, or **Process**, to an instance of Analysis Services. This command language is discussed in the [XML for Analysis \(XMLA\) Reference](#).

To view the ASSL that describes a multidimensional solution in SQL Server Data Tools, you can use the View Code command at the project level. You can also create or edit ASSL script in Management Studio using the XMLA query editor. The scripts you build can be used to manage objects or run commands on the server.

ASSL Objects and Object Characteristics

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Objects in Analysis Services Scripting Language (ASSL) follow specific guidelines in regards to object groups, inheritance, naming, expansion, and processing.

Object Groups

All Microsoft SQL Server SQL Server Analysis Services objects have an XML representation. The objects are divided into two groups:

Major objects

Major objects can be independently created, altered, and deleted. Major objects include:

- Servers
- Databases
- Dimensions
- Cubes
- Measure groups
- Partitions
- Perspectives
- Mining models
- Roles
- Commands associated with a server or database
- Data sources

Major objects have the following properties to track their history and status.

- **CreatedTimestamp**
- **LastSchemaUpdate**
- **LastProcessed** (where appropriate)

Note

The classification of an object as a major object affects how an instance of SQL Server Analysis Services treats that object and how that object is handled in the object definition language. However, this classification does not guarantee that SQL Server Analysis Services management and development tools will allow the independent creation, modification, or deletion of these objects.

Minor objects

Minor objects can only be created, altered, or deleted as part of creating, altering, or deleting the parent major object. Minor objects include:

- Hierarchies and levels
- Attributes
- Measures
- Mining model columns
- Commands associated with a cube
- Aggregations

Object Expansion

The **ObjectExpansion** restriction can be used to control the degree of expansion of ASSL XML returned by the server. This restriction has the options listed in the following table.

 Expand table

Enumeration value	Allowed for <Alter>	Description
<i>ReferenceOnly</i>	no	Returns only the name, ID, and timestamp for the requested object and for all contained major objects recursively.
<i>ObjectProperties</i>	yes	Expands the requested object and minor contained objects, but does not return major contained objects.
<i>ExpandObject</i>	no	Same as <i>ObjectProperties</i> , but also returns the name, ID, and timestamp for contained major objects.
<i>ExpandFull</i>	yes	Fully expands the requested object and all contained objects recursively.

This ASSL reference section describes the *ExpandFull* representation. All other **ObjectExpansion** levels are derived from this level.

Object Processing

ASSL includes read-only elements or properties (for example, **LastProcessed**) that can be read from the SQL Server Analysis Services instance, but which are omitted when command scripts are submitted to the instance. SQL Server Analysis Services ignores modified values for read-only elements without warning or error.

SQL Server Analysis Services also ignores inappropriate or irrelevant properties without raising validation errors. For example, the X element should only be present when the Y element has a particular value. The SQL Server Analysis Services instance ignores the X element instead of validating that element against the value of the Y element.

Backing Up, Restoring, and Synchronizing Databases (XMLA)

Article • 12/09/2022

In XML for Analysis, there are three commands that back up, restore, and synchronize databases:

- The [Backup](#) command backs up a Microsoft SQL Server SQL Server Analysis Services database using an SQL Server Analysis Services backup file (.abf), as described in the section, [Backing Up Databases](#).
- The [Restore](#) command restores an SQL Server Analysis Services database from an .abf file, as described in the section, [Restoring Databases](#).
- The [Synchronize](#) command synchronizes one SQL Server Analysis Services database with the data and metadata of another database, as described in the section, [Synchronizing Databases](#).

Backing Up Databases

As mentioned earlier, the **Backup** command backs up a specified SQL Server Analysis Services database to a backup file. The **Backup** command has various properties that let you specify the database to be backed up, the backup file to use, how to back up security definitions, and the remote partitions to be backed up.

Important

The Analysis Services service account must have permission to write to the backup location specified for each file. Also, the user must have one of the following roles: administrator role on the SQL Server Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be backed up.

Specifying the Database and Backup File

To specify the database to be backed up, you set the **Object** property of the **Backup** command. The **Object** property must contain an object identifier for a database, or an error occurs.

To specify the file that is to be created and used by the backup process, you set the **File** property of the **Backup** command. The **File** property should be set to a UNC path and file name for the backup file to be created.

Besides specifying which file to use for backup, you can set the following options for the specified backup file:

- If you set the [AllowOverwrite](#) property to true, the **Backup** command overwrites the backup file if the specified file already exists. If you set the [AllowOverwrite](#) property to false, an error occurs if the specified backup file already exists.
- If you set the [ApplyCompression](#) property to true, the backup file is compressed after the file is created.
- If you set the [Password](#) property to any non-blank value, the backup file is encrypted by using the specified password.

 **Important**

If **ApplyCompression** and **Password** properties are not specified, the backup file stores user names and passwords that are contained in connection strings in clear text. Data that is stored in clear text may be retrieved. For increased security, use the **ApplyCompression** and **Password** settings to both compress and encrypt the backup file.

Backing Up Security Settings

The **Security** property determines whether the **Backup** command backs up the security definitions, such as roles and permissions, defined on an SQL Server Analysis Services database. The **Security** property also determines whether the backup file includes the Windows user accounts and groups defined as members of the security definitions.

The value of the **Security** property is limited to one of the strings listed in the following table.

 [Expand table](#)

Value	Description
<i>SkipMembership</i>	Include security definitions, but exclude membership information, in the backup file.
<i>CopyAll</i>	Include security definitions and membership information in the backup file.

Value	Description
<i>IgnoreSecurity</i>	Exclude security definitions from the backup file.

Backing Up Remote Partitions

To back up remote partitions in the SQL Server Analysis Services database, you set the [BackupRemotePartitions](#) property of the **Backup** command to true. This setting causes the **Backup** command to create a remote backup file for each remote data source that is used to store remote partitions for the database.

For each remote data source to be backed up, you can specify its corresponding backup file by including a [Location](#) element in the [Locations](#) property of the **Backup** command. The **Location** element should have its **File** property set to the UNC path and file name of the remote backup file, and its [DataSourceID](#) property set to the identifier of the remote data source defined in the database.

Restoring Databases

The **Restore** command restores a specified SQL Server Analysis Services database from a backup file. The **Restore** command has various properties that let you specify the database to restore, the backup file to use, how to restore security definitions, the remote partitions to be stored, and the relocation relational OLAP (ROLAP) objects.

Important

For each backup file, the user who runs the restore command must have permission to read from the backup location specified for each file. To restore an SQL Server Analysis Services database that is not installed on the server, the user must also be a member of the server role for that SQL Server Analysis Services instance. To overwrite an SQL Server Analysis Services database, the user must have one of the following roles: a member of the server role for the SQL Server Analysis Services instance or a member of a database role with Full Control (Administrator) permissions on the database to be restored.

Note

After restoring an existing database, the user who restored the database might lose access to the restored database. This loss of access can occur if, at the time that the

backup was performed, the user was not a member of the server role or was not a member of the database role with Full Control (Administrator) permissions.

Specifying the Database and Backup File

The **DatabaseName** property of the **Restore** command must contain an object identifier for a database, or an error occurs. If the specified database already exists, the **AllowOverwrite** property determines whether the existing database is overwritten. If the **AllowOverwrite** property is set to false and the specified database already exists, an error occurs.

You should set the **File** property of the **Restore** command to a UNC path and file name for the backup file to be restored to the specified database. You can also set the **Password** property for the specified backup file. If the **Password** property is set to any non-blank value, the backup file is decrypted by using the specified password. If the backup file was not encrypted, or if the specified password does not match the password used to encrypt the backup file, an error occurs.

Restoring Security Settings

The **Security** property determines whether the **Restore** command restores the security definitions, such as roles and permissions, defined on an SQL Server Analysis Services database. The **Security** property also determines whether the **Restore** command includes the Windows user accounts and groups defined as members of the security definitions as part of the restore process.

The value of this element is limited to one of the strings listed in the following table.

[+] Expand table

Value	Description
<i>SkipMembership</i>	Include security definitions, but exclude membership information, in the database.
<i>CopyAll</i>	Include security definitions and membership information in the database.
<i>IgnoreSecurity</i>	Exclude security definitions from the database.

Restoring Remote Partitions

For each remote backup file created during a previous **Backup** command, you can restore its associated remote partition by including a **Location** element in the **Locations** property of the **Restore** command. The **DataSourceType** property for each **Location** element must be excluded or explicitly set to *Remote*.

For each specified **Location** element, the SQL Server Analysis Services instance contacts the remote data source specified in the **DataSourceID** property to restore the partitions defined in the remote backup file specified in the **File** property. Besides the **DataSourceID** and **File** properties, the following properties are available for each **Location** element used to restore a remote partition:

- To override the connection string for the remote data source specified in **DataSourceID**, you can set the **ConnectionString** property of the **Location** element to a different connection string. The **Restore** command will then use the connection string that is contained in the **ConnectionString** property. If **ConnectionString** is not specified, the **Restore** command uses the connection string stored in the backup file for the specified remote data source. You can use the **ConnectionString** setting to move a remote partition to a different remote instance. However, you cannot use the **ConnectionString** setting to restore a remote partition to the same instance that contains the restored database. In other words, you cannot use the **ConnectionString** property to make a remote partition into a local partition.
- For each original folder used to store the remote partitions on the remote data source, you can specify a **Folder** element to indicate the new folder in which to restore all the remote partitions stored in the original folder. If a **Folder** element is not specified, the **Restore** command uses the original folders specified for the remote partitions that are contained in the remote backup file.

Relocating ROLAP Objects

The **Restore** command cannot restore aggregations or data for objects that use ROLAP storage because such information is stored in tables on an underlying relational data source. However, the metadata for ROLAP objects can be restored. To restore the metadata for ROLAP object, the **Restore** command re-creates the table structure on a relational data source.

You can use the **Location** element in a **Restore** command to relocate ROLAP objects. For each **Location** element used to relocate a data source, the **DataSourceType** property must be explicitly set to *Local*. You also have to set the **ConnectionString** property of the **Location** element to the connection string of the new location. During the restore, the **Restore** command will replace the connection string for the data source identified by

the **DataSourceID** property of the **Location** element with the value of the **ConnectionString** property of the **Location** element.

Synchronizing Databases

The **Synchronize** command synchronizes the data and metadata of a specified SQL Server Analysis Services database with another database. The **Synchronize** command has various properties that let you specify the source database, how to synchronize security definitions, the remote partitions to be synchronized, and the synchronization of ROLAP objects.

Note

The **Synchronize** command can be executed only by server administrators and database administrators. Both the source and destination database must have the same database compatibility level.

Specifying the Source Database

The **Source** property of the **Synchronize** command contains two properties, **ConnectionString** and **Object**. The **ConnectionString** property contains the connection string of the instance that contains the source database, and the **Object** property contains the object identifier for the source database.

The destination database is the current database for the session in which the **Synchronize** command runs.

If the **ApplyCompression** property of the **Synchronize** command is set to true, the information sent from the source database to the destination database is compressed before being sent.

Synchronizing Security Settings

The **SynchronizeSecurity** property determines whether the **Synchronize** command synchronizes the security definitions, such as roles and permissions, defined on the source database. The **SynchronizeSecurity** property also determines whether the **Synchronize** command includes the Windows user accounts and groups defined as members of the security definitions.

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>SkipMembership</i>	Include security definitions, but exclude membership information, in the destination database.
<i>CopyAll</i>	Include security definitions and membership information in the destination database.
<i>IgnoreSecurity</i>	Exclude security definitions from the destination database.

Synchronizing Remote Partitions

For each remote data source that exists on the source database, you can synchronize each associated remote partition by including a **Location** element in the **Locations** property of the **Synchronize** command. For each **Location** element, the **DataSourceType** property must be excluded or explicitly set to *Remote*.

To define and connect to a remote data source in the destination database, the **Synchronize** command uses the connection string defined in the **ConnectionString** property of the **Location** element. The **Synchronize** command then uses the **DataSourceID** property of the **Location** element to identify which remote partitions to synchronize. The **Synchronize** command synchronizes the remote partitions on the remote data source specified in the **DataSourceID** property on the source database with the remote data source specified in the **DataSourceID** property on the destination database.

For each original folder used to store the remote partitions on the remote data source on the source database, you can also specify a **Folder** element in the **Location** element. The **Folder** element indicates the new folder for the destination database in which to synchronize all the remote partitions stored in the original folder on the remote data source. If a **Folder** element is not specified, the **Synchronize** command uses the original folders specified for remote partitions that are contained in the source database.

Synchronizing ROLAP Objects

The **Synchronize** command cannot synchronize aggregations or data for objects that use ROLAP storage because such information is stored in tables on an underlying relational data source. However, the metadata for ROLAP objects can be synchronized. To synchronize the metadata, the **Synchronize** command recreates the table structure on a relational data source.

You can use the **Location** element in a Synchronize command to synchronize ROLAP objects. For each **Location** element used to relocate a data source, the **DataSourceType** property must be explicitly set to *Local*. You also have to set the **ConnectionString** property of the **Location** element to the connection string of the new location. During synchronization, the **Synchronize** command will replace the connection string for the data source identified by the **DataSourceID** property of the **Location** element with the value of the **ConnectionString** property of the **Location** element.

Cancelling Commands (XMLA)

Article • 12/09/2022

Depending on the administrative permissions of the user issuing the command, the [Cancel](#) command in XML for Analysis (XMLA) can cancel a command on a session, a session, a connection, a server process, or an associated session or connection.

Cancelling Commands

A user can cancel the currently executing command within the context of the current explicit session by sending a [Cancel](#) command with no specified properties.

 **Note**

A command running in an implicit session cannot be canceled by a user.

Cancelling Batch Commands

If a user cancels a [Batch](#) command, then all remaining commands not yet executed within the [Batch](#) command are canceled. If the [Batch](#) command was transactional, any commands that were executed before the [Cancel](#) command runs are rolled back.

Cancelling Sessions

By specifying a session identifier for an explicit session in the [SessionID](#) property of the [Cancel](#) command, a database administrator or server administrator can cancel a session, including the currently executing command. A database administrator can only cancel sessions for databases on which he or she has administrative permissions.

A database administrator can retrieve the active sessions for a specified database by retrieving the [DISCOVER_SESSIONS](#) schema rowset. To retrieve the [DISCOVER_SESSIONS](#) schema rowset, the database administrator uses the XMLA [Discover](#) method and specifies the appropriate database identifier for the [SESSION_CURRENT_DATABASE](#) restriction column in the [Restrictions](#) property of the [Discover](#) method.

Cancelling Connections

By specifying a connection identifier in the [ConnectionID](#) property of the [Cancel](#) command, a server administrator can cancel all of the sessions associated with a given connection, including all running commands, and cancel the connection.

Note

If the instance of MicrosoftSQL ServerSQL Server Analysis Services cannot locate and cancel the sessions associated with a connection, such as when the data pump opens multiple sessions while providing HTTP connectivity, the instance cannot cancel the connection. If this case is encountered during the execution of a [Cancel](#) command, an error occurs.

A server administrator can retrieve the active connections for an SQL Server Analysis Services instance by retrieving the `DISCOVER_CONNECTIONS` schema rowset using the [XMLA Discover](#) method.

Canceling Server Processes

By specifying a server process identifier (SPID) in the [SPID](#) property of the [Cancel](#) command, a server administrator can cancel the commands associated with a given SPID.

Canceling Associated Sessions and Connections

You can set the [CancelAssociated](#) property to true to cancel the connections, sessions, and commands associated with the connection, session, or SPID specified in the [Cancel](#) command.

Creating and Altering Objects (XMLA)

Article • 12/09/2022

Major objects can be independently created, altered, and deleted. Major objects include the following objects:

- Servers
- Databases
- Dimensions
- Cubes
- Measure groups
- Partitions
- Perspectives
- Mining models
- Roles
- Commands associated with a server or database
- Data sources

You use the [Create](#) command to create a major object on an instance of Microsoft SQL Server SQL Server Analysis Services, and the [Alter](#) command to alter an existing major object on an instance. Both commands are run using the [Execute](#) method.

Creating Objects

When you create objects by using the [Create](#) method, you must first identify the parent object that contains the SQL Server Analysis Services object to be created. You identify the parent object by providing an object reference in the [ParentObject](#) property of the [Create](#) command. Each object reference contains the object identifiers needed to uniquely identify the parent object for the [Create](#) command. For more information about object references, see [Defining and Identifying Objects \(XMLA\)](#).

For example, you must provide an object reference to a cube to create a new measure group for the cube. The object reference for the cube in the [ParentObject](#) property

contains both a database identifier and a cube identifier, as the same cube identifier could potentially be used on a different database.

The **ObjectDefinition** element contains Analysis Services Scripting Language (ASSL) elements that define the major object to be created. For more information about ASSL, see [Developing with Analysis Services Scripting Language \(ASSL\)](#).

If you set the **AllowOverwrite** attribute of the **Create** command to true, you can overwrite an existing major object that has the specified identifier. Otherwise, an error occurs if a major object that has the specified identifier already exists in the parent object.

For more information about the **Create** command, see [Create Element \(XMLA\)](#).

Creating Session Objects

Session objects are temporary objects that are available only to the explicit or implicit session used by a client application and are deleted when the session is ended. You can create session objects by setting the **Scope** attribute of the **Create** command to *Session*.

ⓘ Note

When using the *Session* setting, the **ObjectDefinition** element can only contain [Dimension](#), [Cube](#), or [MiningModel](#) ASSL elements.

Altering Objects

When modifying objects by using the **Alter** method, you must first identify the object to be modified by providing an object reference in the **Object** property of the **Alter** command. Each object reference contains the object identifiers needed to uniquely identify the object for the **Alter** command. For more information about object references, see [Defining and Identifying Objects \(XMLA\)](#).

For example, you must provide an object reference to a cube in order to modify the structure of a cube. The object reference for the cube in the **Object** property contains both a database identifier and a cube identifier, as the same cube identifier could potentially be used on a different database.

The **ObjectDefinition** element contains ASSL elements that define the major object to be modified. For more information about ASSL, see [Developing with Analysis Services Scripting Language \(ASSL\)](#).

If you set the **AllowCreate** attribute of the **Alter** command to true, you can create the specified major object if the object does not exist. Otherwise, an error occurs if a specified major object does not already exist.

Using the ObjectExpansion Attribute

If you are changing only the properties of the major object and are not redefining minor objects that are contained by the major object, you can set the **ObjectExpansion** attribute of the **Alter** command to *ObjectProperties*. The **ObjectDefinition** property then only has to contain the elements for the properties of the major object, and the **Alter** command leaves minor objects associated with the major object untouched.

To redefine minor objects for a major object, you must set the **ObjectExpansion** attribute to *ExpandFull* and the object definition must include all minor objects that are contained by the major object. If the **ObjectDefinition** property of the **Alter** command does not explicitly include a minor object that is contained by the major object, the minor object that was not included is deleted.

Altering Session Objects

To modify session objects created by the **Create** command, set the **Scope** attribute of the **Alter** command to *Session*.

 **Note**

When using the *Session* setting, the **ObjectDefinition** element can only contain [Dimension](#), [Cube](#), or [MiningModel](#) ASSL elements.

Creating or Altering Subordinate Objects

Although a **Create** or **Alter** command creates or alters only one topmost major object, the major object being created or modified can contain definitions within the enclosing **ObjectDefinition** property for other major and minor objects that are subordinate to it. For example, if you define a cube, you specify the parent database in **ParentObject**, and within the cube definition in **ObjectDefinition** you can define measure groups for the cube, and within the measure groups you can define partitions for each measure group. A minor object can be defined only under the major object that contains it. For more information about major and minor objects, see [Database Objects \(Analysis Services - Multidimensional Data\)](#).

Examples

Description

The following example creates a relational data source that references the Adventure Works DW Multidimensional 2012 sample Microsoft SQL Server database.

Code

```
<Create xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <ParentObject>
    <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
  </ParentObject>
  <ObjectDefinition>
    <DataSource xmlns:xsd="http://www.w3.org/2001/XMLSchema"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:type="RelationalDataSource">
      <ID>AdventureWorksDW2012</ID>
      <Name>AdventureWorksDW2012</Name>
      <ConnectionString>Data Source=localhost;Initial
        Catalog=AdventureWorksDW2008R2;Integrated Security=True</ConnectionString>
      <ImpersonationInfo>

      <ImpersonationMode>ImpersonateServiceAccount</ImpersonationMode>
      </ImpersonationInfo>
      <ManagedProvider>System.Data.SqlClient</ManagedProvider>
      <Timeout>PT0S</Timeout>
    </DataSource>
  </ObjectDefinition>
</Create>
```

Description

The following example alters the relational data source created in the previous example to set the query time-out for the data source to 30 seconds.

Code

```
<Alter ObjectExpansion="ObjectProperties"
  xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Object>
    <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
```

```
<DataSourceID>AdventureWorksDW2012</DataSourceID>
</Object>
<ObjectDefinition>
    <DataSource xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:type="RelationalDataSource">
        <ID>AdventureWorksDW2012</ID>
        <Name>AdventureWorksDW2012</Name>
        <ConnectionString>Data Source=fr-dwk-02;Initial
Catalog=AdventureWorksDW2008R2;Integrated Security=True</ConnectionString>
        <ManagedProvider>System.Data.SqlClient</ManagedProvider>
        <Timeout>PT30S</Timeout>
    </DataSource>
</ObjectDefinition>
</Alter>
```

Comments

The **ObjectExpansion** attribute of the **Alter** command was set to *ObjectProperties*. This setting allows the **ImpersonationInfo** element, a minor object, to be excluded from the data source defined in **ObjectDefinition**. Therefore, the impersonation information for that data source remains set to the service account, as specified in the first example.

Defining and Identifying Objects (XMLA)

Article • 12/09/2022

Objects are identified in XML for Analysis (XMLA) commands by using object identifiers and object references, and are defined by using Analysis Services Scripting Language (ASSL) elements XMLA commands.

Object Identifiers

An object is identified by using the unique identifier of the object as defined on an instance of Microsoft SQL Server SQL Server Analysis Services. Object identifiers can either be explicitly specified or determined by the SQL Server Analysis Services instance when SQL Server Analysis Services creates the object. You can use the [Discover](#) method to retrieve object identifiers for subsequent [Discover](#) or [Execute](#) method calls.

Object References

Several XMLA commands, such as [Delete](#) or [Process](#), use an object reference to refer to an object in an unambiguous manner. An object reference contains the object identifier of the object on which a command is executed and the object identifiers of the ancestors for that object. For example, the object reference for a partition contains the object identifier of the partition, as well as the object identifiers of that partition's parent measure group, cube, and database.

Object Definitions

The [Create](#) and [Alter](#) commands in XMLA create or alter, respectively, objects on an SQL Server Analysis Services instance. The definitions for those objects are represented by an [ObjectDefinition](#) element that contains elements from ASSL. Object identifiers can be explicitly specified for all major and many minor objects by using the [ID](#) element. If the [ID](#) element is not used, the SQL Server Analysis Services instance provides a unique identifier, with a naming convention that depends on the object to be identified. For more information about how to use the [Create](#) and [Alter](#) commands to define objects, see [Creating and Altering Objects \(XMLA\)](#).

Designing Aggregations (XMLA)

Article • 12/09/2022

Aggregation designs are associated with the partitions of a particular measure group to make sure that the partitions use the same structure when storing aggregations. Using the same storage structure for partitions lets you easily define partitions that can be later merged using the [MergePartitions](#) command. For more information about aggregation designs, see [Aggregations and Aggregation Designs](#).

To define aggregations for an aggregation design, you can use the [DesignAggregations](#) command in XML for Analysis (XMLA). The **DesignAggregations** command has properties that identify which aggregation design to use as a reference and how to control the design process based upon that reference. Using the **DesignAggregations** command and its properties, you can design aggregations iteratively or in batch, and then view the resulting design statistics to evaluate the design process.

Specifying an Aggregation Design

The [Object](#) property of the **DesignAggregations** command must contain an object reference to an existing aggregation design. The object reference contains a database identifier, cube identifier, measure group identifier, and aggregation design identifier. If the aggregation design does not already exist, an error occurs.

Controlling the Design Process

You can use the following properties of the **DesignAggregations** command to control the algorithm used to define aggregations for the aggregation design:

- The [Steps](#) property determines how many iterations the **DesignAggregations** command should take before it returns control to the client application.
- The [Time](#) property determines how many milliseconds the **DesignAggregations** command should take before it returns control to the client application.
- The [Optimization](#) property determines the estimated percentage of performance improvement the **DesignAggregations** command should try to achieve. If you are iteratively designing aggregations, you only have to send this property on the first command.
- The [Storage](#) property determines the estimated amount of disk storage, in bytes, used by the **DesignAggregations** command. If you are iteratively designing

aggregations, you only have to send this property on the first command.

- The **Materialize** property determines whether the **DesignAggregations** command should create the aggregations defined during the design process. If you are iteratively designing aggregations, this property should be set to false until you are ready to save the designed aggregations. When set to true, the current design process ends and the defined aggregations are added to the specified aggregation design.

Specifying Queries

The **DesignAggregations** command supports usage-based optimization command by including one or more **Query** elements in the **Queries** property. The **Queries** property can contain one or more **Query** elements. If the **Queries** property does not contain any **Query** elements, the aggregation design specified in the **Object** element uses a default structure that contains a general set of aggregations. This general set of aggregations is designed to meet the criteria specified in the **Optimization** and **Storage** properties of the **DesignAggregations** command.

Each **Query** element represents a goal query that the design process uses to define aggregations that target the most frequently used queries. You can either specify your own goal queries, or you can use the information stored by an instance of Microsoft SQL Server SQL Server Analysis Services in the query log to retrieve information about the most frequently used queries. The Usage-Based Optimization Wizard uses the query log to retrieve goal queries based on time, usage, or a specified user when it sends a **DesignAggregations** command. For more information, see [Usage-Based Optimization Wizard F1 Help](#).

If you are iteratively designing aggregations, you only have to pass goal queries in the first **DesignAggregations** command because the SQL Server Analysis Services instance stores these goal queries and uses these queries during subsequent **DesignAggregations** commands. After you pass goal queries in the first **DesignAggregations** command of an iterative process, any subsequent **DesignAggregations** command that contains goal queries in the **Queries** property generates an error.

The **Query** element contains a comma-delimited value that contains the following arguments:

Frequency, Dataset[, Dataset...]

Frequency

A weighting factor that corresponds to the number of times that the query has previously been executed. If the **Query** element represents a new query, the *Frequency* value represents the weighting factor used by the design process to evaluate the query. As the frequency value becomes larger, the weight that is put on the query during the design process increases.

Dataset

A numeric string that specifies which attributes from a dimension are to be included in the query. This string must have the same number of characters as the number of attributes in the dimension. Zero (0) indicates that the attribute in the specified ordinal position is not included in the query for the specified dimension, while one (1) indicates that the attribute in the specified ordinal position is included in the query for the specified dimension.

For example, the string "011" would refer to a query involving a dimension with three attributes, from which the second and third attributes are included in the query.

Note

Some attributes are excluded from consideration in the dataset. For more information about excluded attributes, see [Query Element \(XMLA\)](#).

Each dimension in the measure group that contains the aggregation design is represented by a *Dataset* value in the **Query** element. The order of *Dataset* values must match the order of dimensions included in the measure group.

Designing Aggregations Using Iterative or Batch Processes

You can use the **DesignAggregations** command as part of an iterative process or a batch process, depending on the interactivity required by the design process.

Designing Aggregations Using an Iterative Process

To iteratively design aggregations, you send multiple **DesignAggregations** commands to provide fine control over the design process. The Aggregation Design Wizard uses this same approach to provide fine control over the design process. For more information, see [Aggregation Design Wizard F1 Help](#).

Note

An explicit session is required to iteratively design aggregations. For more information about explicit sessions, see [Managing Connections and Sessions \(XMLA\)](#).

To start the iterative process, you first send a **DesignAggregations** command that contains the following information:

- The **Storage** and **Optimization** property values on which the whole design process is targeted.
- The **Steps** and **Time** property values on which the first step of the design process is limited.
- If you want usage-based optimization, the **Queries** property that contains the goal queries on which the whole design process is targeted.
- The **Materialize** property set to false. Setting this property to false indicates that the design process does not save the defined aggregations to the aggregation design when the command is completed.

When the first **DesignAggregations** command finishes, the command returns a rowset that contains design statistics. You can evaluate these design statistics to determine whether the design process should continue or whether the design process is finished. If the process should continue, you then send another **DesignAggregations** command that contains the **Steps** and **Time** values with which this step of the design process is limited. You evaluate the resulting statistics and then determine whether the design process should continue. This iterative process of sending **DesignAggregations** commands and evaluating the results continues until you reach your goals and have an appropriate set of aggregations defined.

After you have reached the set of aggregations that you want, you send one final **DesignAggregations** command. This final **DesignAggregations** command should have its **Steps** property set to 1 and its **Materialize** property set to true. By using these settings, this final **DesignAggregations** command completes the design process and saves the defined aggregation to the aggregation design.

Designing Aggregations Using a Batch Process

You can also design aggregations in a batch process by sending a single **DesignAggregations** command that contains the **Steps**, **Time**, **Storage**, and

Optimization property values on which the whole design process is targeted and limited. If you want usage-based optimization, the goal queries on which the design process is targeted should also be included in the **Queries** property. Also make sure that the **Materialize** property is set to true, so that the design process saves the defined aggregations to the aggregation design when the command finishes.

You can design aggregations using a batch process in either an implicit or explicit session. For more information about implicit and explicit sessions, see [Managing Connections and Sessions \(XMLA\)](#).

Returning Design Statistics

When the **DesignAggregations** command returns control to the client application, the command returns a rowset that contains a single row representing the design statistics for the command. The rowset contains the columns listed in the following table.

[\[+\] Expand table](#)

Column	Data type	Description
Steps	Integer	The number of steps taken by the command before returning control to the client application.
Time	Long integer	The number of milliseconds taken by the command before returning control to the client application.
Optimization	Double	The estimated percentage of performance improvement achieved by the command before returning control to the client application.
Storage	Long integer	The estimated number of bytes taken by the command before returning control to the client application.
Aggregations	Long integer	The number of aggregations defined by the command before returning control to the client application.
LastStep	Boolean	Indicates whether the data in the rowset represents the last step in the design process. If the Materialize property of the command was set to true, the value of this column is set to true.

You can use the design statistics that are contained in the rowset returned after each **DesignAggregations** command in both iterative and batch design. In iterative design, you can use the design statistics to determine and display progress. When you are designing aggregations in batch, you can use the design statistics to determine the number of aggregations created by the command.

Developing with XMLA in Analysis Services

Article • 12/09/2022

XML for Analysis (XMLA) is a SOAP-based XML protocol, designed specifically for universal data access to any standard multidimensional data source that can be accessed over an HTTP connection. SQL Server Analysis Services uses XMLA as its only protocol when communicating with client applications. Fundamentally, all client libraries supported by Analysis Services formulate requests and responses in XMLA.

As a developer, you can use XMLA to integrate a client application with SQL Server Analysis Services, without any dependencies on the .NET Framework or COM interfaces. Application requirements that include hosting on a wide range of platforms can be satisfied by using XMLA and an HTTP connection to SQL Server Analysis Services.

SQL Server Analysis Services is fully compliant with the 1.1 specification of XMLA, but also extends it to enable data definition, data manipulation, and data control support. Analysis Services extensions are referred to as the Analysis Services Scripting Language (ASSL). Using XMLA and ASSL together enables a broader set of functionality than what XMLA alone provides. For more information about ASSL, see [Developing with Analysis Services Scripting Language \(ASSL\)](#).

In This Section

[] [Expand table](#)

Topic	Description
Managing Connections and Sessions (XMLA)	Describes how to connect to an SQL Server Analysis Services instance, and how to manage sessions and statefulness in XMLA.
Handling Errors and Warnings (XMLA)	Describes how SQL Server Analysis Services returns error and warning information for methods and commands in XMLA.
Defining and Identifying Objects (XMLA)	Describes object identifiers and object references, and how to use identifiers and references within XMLA commands.
Managing Transactions (XMLA)	Details how to use the BeginTransaction , CommitTransaction , and RollbackTransaction commands to explicitly define and manage a transaction on the current XMLA session.
Canceling Commands (XMLA)	Describes how to use the Cancel command to cancel commands, sessions, and connections in XMLA.

Topic	Description
Performing Batch Operations (XMLA)	Describes how to use the Batch command to run multiple XMLA commands, in serial or in parallel, either within the same transaction or as separate transactions, using a single XMLA Execute method.
Creating and Altering Objects (XMLA)	Describes how to use the Create , Alter , and Delete commands, along with Analysis Services Scripting Language (ASSL) elements, to define, change, or remove objects from an SQL Server Analysis Services instance.
Locking and Unlocking Databases (XMLA)	Details how to use the Lock and Unlock commands to lock and unlock an SQL Server Analysis Services database.
Processing Objects (XMLA)	Describes how to use the Process command to process an SQL Server Analysis Services object.
Merging Partitions (XMLA)	Describes how to use the MergePartitions command to merge partitions on an SQL Server Analysis Services instance.
Designing Aggregations (XMLA)	Describes how to use the DesignAggregations command, either in iterative or batch mode, to design aggregations for an aggregation design in SQL Server Analysis Services.
Backing Up, Restoring, and Synchronizing Databases (XMLA)	Describes how to use the Backup and Restore commands to back up and restore an SQL Server Analysis Services database from a backup file. Also describes how to use the Synchronize command to synchronize an SQL Server Analysis Services database with an existing database on the same instance or on a different instance.
Inserting, Updating, and Dropping Members (XMLA)	Describes how to use the Insert , Update , and Drop commands to add, change, or delete members from a write-enabled dimension.
Updating Cells (XMLA)	Describes how to use the UpdateCells command to change the values of cells in a write-enabled partition.
Managing Caches (XMLA)	Details how to use the ClearCache command to clear the caches of SQL Server Analysis Services objects.
Monitoring Traces (XMLA)	Describes how to use the Subscribe command to subscribe to and monitor an existing trace on an SQL Server Analysis Services instance.

Data Mining with XMLA

XML for Analysis fully supports data mining schema rowsets. These rowsets provide information for querying data mining models using the [Discover](#) method.

For more information about DMX, see [Data Mining Extensions \(DMX\) Reference](#).

Namespace and Schema

Namespace

The schema defined in this specification uses the XML namespace

`http://schemas.microsoft.com/AnalysisServices/2003/Engine` and the standard abbreviation "DDL."

Schema

The definition of an XML Schema definition language (XSD) schema for the SQL Server Analysis Services object definition language is based on the definition of the schema elements and hierarchy in this section.

Extensibility

Extensibility of the object definition language schema is provided by means of an **Annotation** element that is included on all objects. This element can contain any valid XML from any XML namespace (other than the target namespace that defines the DDL), subject to the following rules:

- The XML can contain only elements.
- Each element must have a unique name. It is recommended that the value of **Name** reference the target namespace.

These rules are imposed so that the contents of the **Annotation** tag can be exposed as a set of Name/Value pairs through Decision Support Objects (DSO) 9.0.

Comments and white space within the **Annotation** tag that are not enclosed with a child element may not be preserved. In addition, all elements must be read-write; read-only elements are ignored.

The object definition language schema is closed, in that the server does not allow substitution of derived types for elements defined in the schema. Therefore, the server accepts only the set of elements defined here, and no other elements or attributes. Unknown elements cause the SQL Server Analysis Services engine to raise an error.

Handling Errors and Warnings (XMLA)

Article • 12/09/2022

Error handling is required when an XML for Analysis (XMLA) [Discover](#) or [Execute](#) method call does not run, runs successfully but generates errors or warnings, or runs successfully but returns results that contain errors.

[+] [Expand table](#)

Error	Reporting
The XMLA method call does not run	<p>Microsoft SQL Server SQL Server Analysis Services returns a SOAP fault message that contains the details of the failure.</p> <p>For more information, see the section, Handling SOAP Faults.</p>
Errors or warnings on a successful method call	<p>SQL Server Analysis Services includes an error or warning element for each error or warning, respectively, in the Messages property of the root element that contains the results of the method call.</p> <p>For more information, see the section, Handling Errors and Warnings.</p>
Errors in the result for a successful method call	<p>SQL Server Analysis Services includes an inline error or warning element for the error or warning, respectively, within the appropriate Cell or row element of the results of the method call.</p> <p>For more information, see the section, Handling Inline Errors and Warnings.</p>

Handling SOAP Faults

SQL Server Analysis Services returns a SOAP fault when the following situations occur:

- The SOAP message that contains the XMLA method was not well-formed or could not be validated by the SQL Server Analysis Services instance.
- A communications or other error occurred involving the SOAP message that contains the XMLA method.
- The XMLA method did not run on the SQL Server Analysis Services instance.

The SOAP fault codes for XMLstartA start with "XMLForAnalysis", followed by a period and the hexadecimal HRESULT result code. For example, an error code of "`0x80000005`"

is formatted as "`XMLForAnalysis.0x80000005`". For more information about the SOAP fault format, see Soap Fault in the W3C Simple Object Access Protocol (SOAP) 1.1.

Fault Code Information

The following table shows the XMLA fault code information that is contained in the detail section of the SOAP response. The columns are the attributes of an error in the detail section of a SOAP fault.

[+] Expand table

Column name	Type	Description	Null allowed ¹
ErrorCode	UnsignedInt	Return code that indicates the success or failure of the method. The hexadecimal value must be converted to an <code>UnsignedInt</code> value.	No
WarningCode	UnsignedInt	Return code that indicates a warning condition. The hexadecimal value must be converted to an <code>UnsignedInt</code> value.	Yes
Description	String	Error or warning text and description returned by the component that generated the error.	Yes
Source	String	Name of the component that generated the error or warning.	Yes
HelpFile	String	Path or URL to the Help file or topic that describes the error or warning.	Yes

¹ Indicates whether the data is required and must be returned, or whether the data is optional and a null string is allowed if the column does not apply.

The following is an example of a SOAP fault that occurred when a method call failed:

```
<?xml version="1.0"?>
<SOAP-ENV:Envelope
  xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
  SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP-ENV:Fault>
    <faultcode>XMLAnalysisError.0x80000005</faultcode>
    <faultstring>The XML for Analysis provider encountered an error.</faultstring>
    <faultactor>XML for Analysis Provider</faultactor>
    <detail>
```

```
<Error  
ErrorCode="2147483653"  
Description="An unexpected error has occurred."  
Source="XML for Analysis Provider"  
HelpFile="" />  
    </detail>  
</SOAP-ENV:Fault>  
</SOAP-ENV:Envelope>
```

Handling Errors and Warnings

SQL Server Analysis Services returns the **Messages** property in the **root** element for a command if the following situations occur after that command runs:

- The method itself did not fail, but a failure occurred on the SQL Server Analysis Services instance after the method call succeeded.
- The SQL Server Analysis Services instance returns a warning when the command is successful.

The **Messages** property follows all other properties that are contained by the **root** element, and can contain one or more **Message** elements. In turn, each **Message** element can contain either a single **error** or **warning** element describing any errors or warnings, respectively, that occurred for the specified command.

For more information about errors and warnings that are contained in the **Messages** property, see [Messages Element \(XMLA\)](#).

Handling Errors During Serialization

If an error occurs after the SQL Server Analysis Services instance has already begun serializing the output of a successfully run command, SQL Server Analysis Services returns an **Exception** element in a different namespace at the point of the error. The SQL Server Analysis Services instance then closes all open elements so that the XML document sent to the client is a valid document. The instance also returns a **Messages** element that contains the description of the error.

Handling Inline Errors and Warnings

SQL Server Analysis Services returns an inline **error** or **warning** for a command if the XMLA method itself did not fail, but an error specific to a data element in the results returned by the method occurred on the SQL Server Analysis Services instance after the XMLA method call succeeded.

SQL Server Analysis Services supplies inline **error** and **warning** elements if issues specific to a cell or to other data that are contained within a **root** element using the [MDDataSet](#) data type occur, such as a security error or formatting error for a cell. In these cases, SQL Server Analysis Services returns an **error** or **warning** element in the **Cell** or **row** element that contains the error or warning, respectively.

The following example illustrates a result set that contains an error in the rowset returned from an **Execute** method using the [Statement](#) command.

```
<return>
...
<root>
...
<CellData>
...
<Cell CellOrdinal="10">
    <Value>
        <Error>
            <ErrorCode>2148497527</ErrorCode>
            <Description>Security Error.</Description>
        </Error>
    </Value>
</Cell>
</CellData>
...
</root>
...
</return>
```

Inserting, Updating, and Dropping Members (XMLA)

Article • 12/09/2022

You can use the [Insert](#), [Update](#), and [Drop](#) commands in XML for Analysis (XMLA) to respectively insert, update, or delete members from a write-enabled dimension. For more information about write-enabled dimensions, see [Write-Enabled Dimensions](#).

Inserting New Members

The **Insert** command inserts new members into specified attributes in a write-enabled dimension.

Before constructing the **Insert** command, you should have the following information available for the new members to be inserted:

- The dimension in which to insert the new members.
- The dimension attribute in which to insert the new members.
- The names of the new members, including any applicable translations for the name.
- The keys of the new members. If an attribute uses a composite key, the key may require multiple values.
- Values for any applicable attribute properties that are not implemented as other attributes within the dimension. Such attribute properties include unary operations, translations, custom rollups, custom rollup properties, and skipped levels.

The **Insert** command takes only two properties:

- The [Object](#) property, which contains an object reference for the dimension in which the members are to be inserted. The object reference contains the database identifier, cube identifier, and dimension identifier for the dimension.
- The [Attributes](#) property, which contains one or more [Attribute](#) elements to identify the attributes in which members are to be inserted. Each [Attribute](#) element identifies an attribute and provides the name, value, translations, unary operator, custom rollup, custom rollup properties, and skipped levels for a single member to be added to the identified attribute.

Note

All properties for the **Attribute** element must be included. Otherwise, an error may occur.

Updating Existing Members

The **Update** command updates existing members in specified attributes, based on relationships with other members in other attributes, in a write-enabled dimension. The **Update** command can move members to other levels in hierarchies contained by the dimension, and can be used to restructure parent-child hierarchies defined by parent attributes.

Before constructing the **Update** command, you should have the following information available for the members to be updated:

- The dimension in which to update existing members.
- The dimension attributes in which to update existing members.
- The keys of the existing members. If an attribute uses a composite key, the key may require multiple values.
- Values for any applicable attribute properties that are not implemented as other attributes within the dimension. Such attribute properties include unary operations, translations, custom rollups, custom rollup properties, and skipped levels.

The **Update** command takes only three required properties:

- The **Object** property, which contains an object reference for the dimension in which the members are to be updated. The object reference contains the database identifier, cube identifier, and dimension identifier for the dimension.
- The **Attributes** property, which contains one or more **Attribute** elements to identify the attributes in which members are to be updated. The **Attribute** element identifies an attribute and provides the name, value, translations, unary operator, custom rollup, custom rollup properties, and skipped levels for a single member updated for the identified attribute.

Note

All properties for the **Attribute** element must be included. Otherwise, an error may occur.

- The [Where](#) property, which contains one or more **Attribute** elements that constrain the attributes in which members are to be updated. The **Where** property is crucial to limiting an **Update** command to specific instances of a member. If the **Where** property is not specified, all instances of a given member are updated. For example, there are three customers for whom you want to change the city name from Redmond to Bellevue. To change the city name, you must provide a **Where** property that identifies the three members in the Customer attribute for which the members in the City attribute should be changed. If you do not provide this **Where** property, every customer whose city name is currently Redmond would have the city name of Bellevue after the **Update** command runs.

 **Note**

With the exception of new members, the **Update** command can only update attribute key values for attributes not included in the **Where** clause. For example, the city name cannot be updated when a customer is updated; otherwise, the city name is changed for all customers.

Updating Members in Parent Attributes

To support parent attributes, the **Update** command the optional [MoveWithDescendants](#) properties. Setting the **MoveWithDescendants** property to true indicates that the descendants of the parent member should also be moved with the parent member when the identifier of that parent member changes. If this value is set to false, moving a parent member causes the immediate descendants of that parent member to be promoted to the level in which the parent member formerly resided.

When updating members in a parent attribute, the **Update** command cannot update members in other attributes.

Dropping Existing Members

Before constructing the **Drop** command, you should have the following information available for the members to be dropped:

- The dimension in which to drop existing members.

- The dimension attributes in which to drop existing members.
- The keys of the existing members to be dropped. If an attribute uses a composite key, the key may require multiple values.

The **Drop** command takes only two required properties:

- The **Object** property, which contains an object reference for the dimension in which the members are to be dropped. The object reference contains the database identifier, cube identifier, and dimension identifier for the dimension.
- The **Where** property, which contains one or more **Attribute** elements to constrain the attributes in which members are to be deleted. The **Where** property is crucial to limiting a **Drop** command to specific instances of a member. If the **Where** command is not specified, all instances of a given member are dropped. For example, there are three customers that you want to drop from Redmond. To drop these customers, you must provide a **Where** property that identifies the three members in the Customer attribute to be removed and the Redmond member of the City attribute from which the three customers are to be removed. If the **Where** property only specifies the Redmond member of the City attribute, every customer associated with Redmond would be dropped by the **Drop** command. If the **Where** property only specifies the three members in the Customer attribute, the three customers would be deleted entirely by the **Drop** command.

 **Note**

The **Attribute** elements included in a **Drop** command must contain only the **AttributeName** and **Keys** properties. Otherwise, an error may occur.

Dropping Members in Parent Attributes

Setting the **DeleteWithDescendants** property indicates that the descendants of a parent member should also be deleted with the parent member. If this value is set to false, the immediate descendants of the parent member are instead promoted to the level in which the parent member formerly resided.

 **Important**

A user needs only to have delete permissions for the parent member to delete both the parent member and its descendants. A user does not need delete permissions on the descendants.

Locking and Unlocking Databases (XMLA)

Article • 12/09/2022

You can lock and unlock databases using, respectively, the [Lock](#) and [Unlock](#) commands in XML for Analysis (XMLA). Typically, other XMLA commands automatically lock and unlock objects as needed to complete the command during execution. You can explicitly lock or unlock a database to perform multiple commands within a single transaction, such as a [Batch](#) command, while preventing other applications from committing a write transaction to the database.

Locking Databases

The **Lock** command locks an object, either for shared or exclusive use, within the context of the currently active transaction. A lock on an object prevents transactions from committing until the lock is removed. Microsoft SQL Server SQL Server Analysis Services supports two types of locks, shared locks and exclusive locks. For more information about the lock types supported by SQL Server Analysis Services, see [Mode Element \(XMLA\)](#).

SQL Server Analysis Services allows only databases to be locked. The [Object](#) element must contain an object reference to an SQL Server Analysis Services database. If the **Object** element is not specified or if the **Object** element refers to an object other than a database, an error occurs.

Important

Only database administrators or server administrators can explicitly issue a **Lock** command.

Other commands implicitly issue a **Lock** command on an SQL Server Analysis Services database. Any operation that reads data or metadata from a database, such as any [Discover](#) method or an [Execute](#) method running a [Statement](#) command, implicitly issues a shared lock on the database. Any transaction that commits changes in data or metadata to an object on an SQL Server Analysis Services database, such as an [Execute](#) method running an [Alter](#) command, implicitly issues an exclusive lock on the database.

Unlocking Objects

The **Unlock** command removes a lock established within the context of the currently active transaction.

ⓘ Important

Only database administrators or server administrators can explicitly issue an **Unlock** command.

All locks are held in the context of the current transaction. When the current transaction is committed or rolled back, all locks defined within the transaction are automatically released.

Managing Caches (XMLA)

Article • 12/09/2022

You can use the [ClearCache](#) command in XML for Analysis (XMLA) to clear the cache of a specified dimension or partition. Clearing the cache forces Microsoft SQL Server SQL Server Analysis Services to rebuild the cache for that object.

Specifying Objects

The [Object](#) property of the [ClearCache](#) command can contain an object reference only for one of the following objects. An error occurs if an object reference is for an object other than one of following objects:

Database

Clears the cache for all dimensions and partitions contained in the database.

Dimension

Clears the cache for the specified dimension.

Cube

Clears the cache for all partitions contained in the measure groups for the cube.

Measure group

Clears the cache for all partitions contained in the measure group.

Partition

Clears the cache for the specified partition.

Managing Connections and Sessions (XMLA)

Article • 12/09/2022

Statefulness is a condition during which the server preserves the identity and context of a client between method calls. *Statelessness* is a condition during which the server does not remember the identity and context of a client after a method call finishes.

To provide statefulness, XML for Analysis (XMLA) supports *sessions* that allow a series of statements to be performed together. An example of such a series of statements would be the creation of a calculated member that is to be used in subsequent queries.

In general, sessions in XMLA follow the following behavior outlined by the OLE DB 2.6 specification:

- Sessions define transaction and command context scope.
- Multiple commands can be run in the context of a single session.
- Support for transactions in the XMLA context is through provider-specific commands sent with the [Execute](#) method.

XMLA defines a way to support sessions in a Web environment in a mode similar to the approach used by the Distributed Authoring and Versioning (DAV) protocol to implement locking in a loosely coupled environment. This implementation parallels DAV in that the provider is allowed to expire sessions for various reasons (for example, a timeout or connection error). When sessions are supported, Web services must be aware and ready to handle interrupted sets of commands that must be restarted.

The World Wide Web Consortium (W3C) Simple Object Access Protocol (SOAP) specification recommends using SOAP headers for building up new protocols on top of SOAP messages. The following table lists the SOAP header elements and attributes that XMLA defines for initiating, maintaining, and closing a session.

[+] Expand table

SOAP header	Description
BeginSession	This header requests the provider to create a new session. The provider should respond by constructing a new session and returning the session ID as part of the Session header in the SOAP response.

SOAP header	Description
SessionId	The value area contains the session ID that must be used in each method call for the rest of the session. The provider in the SOAP response sends this tag and the client must also send this attribute with each Session header element.
Session	For every method call that occurs in the session, this header must be used, and the session ID must be included in the value area of the header.
EndSession	To terminate the session, use this header. The session ID must be included with the value area.

Note

A session ID does not guarantee that a session stays valid. If the session expires (for example, if it times out or the connection is lost), the provider can choose to end and roll back that session's actions. As a result, all subsequent method calls from the client on a session ID fail with an error signaling a session that is not valid. A client should handle this condition and be prepared to resend the session method calls from the beginning.

Legacy Code Example

The following example shows how sessions are supported.

1. To begin the session, add a BeginSession header in SOAP to the outbound XMLA method call from the client. The value area is initially blank because the session ID is not yet known.

```

<SOAP-ENV:Envelope
    xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
    SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
    <SOAP-ENV:Header>
        <XA:BeginSession
            xmlns:XA="urn:schemas-microsoft-com:xml-analysis"
            xsi:type="xsd:int"
            mustUnderstand="1"/>
    </SOAP-ENV:Header>
    <SOAP-ENV:Body>
        ...!-- Discover or Execute call goes here.-->
    </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

2. The SOAP response message from the provider includes the session ID in the return header area, using the XMLA header tag <SessionId>.

```
<SOAP-ENV:Header>
<XA:Session
    xmlns:XA="urn:schemas-microsoft-com:xml-analysis"
    SessionId="581"/>
</SOAP-ENV:Header>
```

3. For each method call in the session, the Session header must be added, containing the session ID returned from the provider.

```
<SOAP-ENV:Header>
<XA:Session
    xmlns:XA="urn:schemas-microsoft-com:xml-analysis"
    mustUnderstand="1"
    SessionId="581"/>
</SOAP-ENV:Header>
```

4. When the session is complete, the <EndSession> tag is used, containing the related session ID value.

```
<SOAP-ENV:Header>
<XA:EndSession
    xmlns:XA="urn:schemas-microsoft-com:xml-analysis"
    xsi:type="xsd:int"
    mustUnderstand="1"
    SessionId="581"/>
</SOAP-ENV:Header>
```

Managing Transactions (XMLA)

Article • 12/09/2022

Every XML for Analysis (XMLA) command sent to an instance of Microsoft SQL Server SQL Server Analysis Services runs within the context of a transaction on the current implicit or explicit session. To manage each of these transactions, you use the [BeginTransaction](#), [CommitTransaction](#), and [RollbackTransaction](#) commands. By using these commands, you can create implicit or explicit transactions, change the transaction reference count, as well as start, commit, or roll back transactions.

Implicit and Explicit Transactions

A transaction is either implicit or explicit:

Implicit transaction

SQL Server Analysis Services creates an *implicit* transaction for an XMLA command if the [BeginTransaction](#) command does not specify the start of a transaction. SQL Server Analysis Services always commits an implicit transaction if the command succeeds, and rolls back an implicit transaction if the command fails.

Explicit transaction

SQL Server Analysis Services creates an *explicit* transaction if the [BeginTransaction](#) command starts of a transaction. However, SQL Server Analysis Services only commits an explicit transaction if a [CommitTransaction](#) command is sent, and rolls back an explicit transaction if a [RollbackTransaction](#) command is sent.

In addition, SQL Server Analysis Services rolls back both implicit and explicit transactions if the current session ends before the active transaction completes.

Transactions and Reference Counts

SQL Server Analysis Services maintains a transaction reference count for each session. However, SQL Server Analysis Services does not support nested transactions in that only one active transaction is maintained per session. If the current session does not have an active transaction, the transaction reference count is set to zero.

In other words, each [BeginTransaction](#) command increments the reference count by one, while each [CommitTransaction](#) command decrements the reference count by one. If a [CommitTransaction](#) command sets the transaction count to zero, SQL Server Analysis Services commits the transaction.

However, the **RollbackTransaction** command rolls back the active transaction regardless of the current value of the transaction reference count. In other words, a single **RollbackTransaction** command rolls back the active transaction, no matter how many **BeginTransaction** commands or **CommitTransaction** commands were sent, and sets the transaction reference count to zero.

Beginning a Transaction

The **BeginTransaction** command begins an explicit transaction on the current session and increments the transaction reference count for the current session by one. All subsequent commands are considered to be within the active transaction, until either enough **CommitTransaction** commands are sent to commit the active transaction or a single **RollbackTransaction** command is sent to roll back the active transaction.

Committing a Transaction

The **CommitTransaction** command commits the results of commands that are run after the **BeginTransaction** command was run on the current session. Each **CommitTransaction** command decrements the reference count for active transactions on a session. If a **CommitTransaction** command sets the reference count to zero, SQL Server Analysis Services commits the active transaction. If there is no active transaction (in other words, the transaction reference count for the current session is already set to zero), a **CommitTransaction** command results in an error.

Rolling Back a Transaction

The **RollbackTransaction** command rolls back the results of commands that are run after the **BeginTransaction** command was run on the current session. The **RollbackTransaction** command rolls back the active transaction, regardless of the current transaction reference count, and sets the transaction reference count to zero. If there is no active transaction (in other words, the transaction reference count for the current session is already set to zero), a **RollbackTransaction** command results in an error.

Merging Partitions (XMLA)

Article • 12/09/2022

If partitions have the same aggregation design and structure, you can merge the partition by using the [MergePartitions](#) command in XML for Analysis (XMLA). Merging partitions is an important action to perform when you manage partitions, especially those partitions that contain historical data partitioned by date.

For example, a financial cube may use two partitions:

- One partition represents financial data for the current year, using real-time relational OLAP (ROLAP) storage settings for performance.
- Another partition contains financial data for previous years, using multidimensional OLAP (MOLAP) storage settings for storage.

Both partitions use different storage settings, but use the same aggregation design. Instead of processing the cube across years of historical data at the end of the year, you can instead use the [MergePartitions](#) command to merge the partition for the current year into the partition for previous years. This preserves the aggregation data without requiring a potentially time-consuming full processing of the cube.

Specifying Partitions to Merge

When the [MergePartitions](#) command runs, the aggregation data stored in the source partitions specified in the [Source](#) property is added to the target partition specified in the [Target](#) property.

Note

The [Source](#) property can contain more than one partition object reference. However, the [Target](#) property cannot.

To be successfully merged, the partitions specified in both the [Source](#) and [Target](#) must be contained by the same measure group and use the same aggregation design. Otherwise, an error occurs.

The partitions specified in the [Source](#) are deleted after the [MergePartitions](#) command is successfully completed.

Examples

Description

The following example merges all the partitions in the **Customer Counts** measure group of the **Adventure Works** cube in the **Adventure Works DW** sample Microsoft SQL Server SQL Server Analysis Services database into the **Customers_2004** partition.

Code

```
<MergePartitions
    xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
    <Sources>
        <Source>
            <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
            <CubeID>Adventure Works DW</CubeID>
            <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
            <PartitionID>Internet_Sales_2001</PartitionID>
        </Source>
        <Source>
            <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
            <CubeID>Adventure Works DW</CubeID>
            <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
            <PartitionID>Internet_Sales_2002</PartitionID>
        </Source>
        <Source>
            <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
            <CubeID>Adventure Works DW</CubeID>
            <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
            <PartitionID>Internet_Sales_2003</PartitionID>
        </Source>

Monitoring Traces (XMLA)

Article • 12/09/2022

You can use the [Subscribe](#) command in XML for Analysis (XMLA) to monitor an existing trace defined on an instance of Microsoft SQL Server SQL Server Analysis Services. The [Subscribe](#) command returns the results of a trace as a rowset.

Specifying a Trace

The [Object](#) property of the [Subscribe](#) command must contain an object reference to either an SQL Server Analysis Services instance or a trace on an SQL Server Analysis Services instance. If the [Object](#) property is not specified, or a trace identifier is not specified in the [Object](#) property, the [Subscribe](#) command monitors the default session trace for the explicit session specified in the SOAP header for the command.

Returning Results

The [Subscribe](#) command returns a rowset containing the trace events captured by the specified trace. The [Subscribe](#) command returns trace results until the command is canceled by the [Cancel](#) command.

The rowset contains the columns listed in the following table.

[Expand table](#)

Column	Data type	Description
EventClass	Integer	The event class of the event received by the trace.
EventSubclass	Long integer	The event subclass of the event received by the trace.
CurrentTime	Datetime	The time at which the event started, when available. For filtering, expected formats are 'YYYY-MM-DD' and 'YYYY-MM-DD HH:MM:SS'.
StartTime	Datetime	The time at which the event started, when available. For filtering, expected formats are 'YYYY-MM-DD' and 'YYYY-MM-DD HH:MM:SS'.
EndTime	Datetime	The time at which the event ended, when available. For filtering, expected formats are 'YYYY-MM-DD' and 'YYYY-MM-DD HH:MM:SS'.

Column	Data type	Description
		This column is not populated for event classes that describe the start of a process or action.
Duration	Long integer	The amount of total time (in milliseconds) elapsed for the event.
CPUTime	Long integer	The amount of processor time (in milliseconds) elapsed for the event.
JobID	Long integer	The job identifier for the process.
SessionID	String	The identifier of the session for which the event occurred.
SessionType	String	The type of the session for which the event occurred.
ProgressTotal	Long integer	The total number or amount of progress reported by the event.
IntegerData	Long integer	Integer data associated with the event. The contents of this column depend on the event class and subclass of the event.
ObjectID	String	The identifier of the object for which the event occurred.
ObjectType	String	The type of the object specified in ObjectName.
ObjectName	String	The name of the object for which the event occurred.
ObjectPath	String	The hierarchical path of the object for which the event occurred. The path is represented as a comma-delimited string of object identifiers for the parents of the object specified in ObjectName.
ObjectReference	String	The XML representation of the object reference for the object specified in ObjectName.
NestLevel	Integer	The level of the transaction for which the event occurred.
NumSegments	Long integer	The number of data segments affected or accessed by the command for which the event occurred.
Severity	Integer	The severity level of an exception for the event. The column can contain one of the following values:
		0: Success

Column	Data type	Description
		1: Information
		2: Warning
		3: Error
Success	Boolean	Indicates whether a command succeeded or failed.
Error	Long integer	The error number of the event, if applicable.
ConnectionID	String	The identifier of the connection for which the event occurred.
DatabaseName	String	The name of the database for which the event occurred.
NTUserName	String	The Windows user name of the user associated with the event.
NTDomainName	String	The Windows domain of the user associated with the event.
ClientHostName	String	The name of the computer on which the client application is running. This column is populated with the values passed by the client application.
ClientProcessID	Long integer	The process identifier of the client application.
ApplicationName	String	The name of the client application that created the connection to the SQL Server Analysis Services instance. This column is populated with the values passed by the client application, rather than the displayed name of the program.
NTCanonicalUserName	String	The Windows canonical user name of the user associated with the event.
SPID	String	The server process ID (SPID) of the session for which the event occurred. The value of this column directly corresponds to the session ID specified in the SOAP header of the XMLA message for which the event occurred.

Column	Data type	Description
TextData	String	The text data associated with the event. The contents of this column depend on the event class and subclass of the event.
ServerName	String	The name of the SQL Server Analysis Services instance for which the event occurred.
RequestParameters	String	The parameters of the parameterized query or XMLA command for which the event occurred.
RequestProperties	String	The properties of the XMLA method for which the event occurred.

Performing Batch Operations (XMLA)

Article • 12/09/2022

You can use the **Batch** command in XML for Analysis (XMLA) to run multiple XMLA commands using a single XMLA **Execute** method. You can run multiple commands contained in the **Batch** command either as a single transaction or in individual transactions for each command, in serial or in parallel. You can also specify out-of-line bindings and other properties in the **Batch** command for processing multiple Microsoft SQL Server SQL Server Analysis Services objects.

Running Transactional and Nontransactional Batch Commands

The **Batch** command executes commands in one of two ways:

Transactional

If the **Transaction** attribute of the **Batch** command is set to true, the **Batch** command runs commands all of the commands contained by the **Batch** command in a single transaction-a *transactional* batch.

If any command fails in a transactional batch, SQL Server Analysis Services rolls back any command in the **Batch** command that ran before the command that failed and the **Batch** command immediately ends. Any commands in the **Batch** command that have not yet run are not executed. After the **Batch** command ends, the **Batch** command reports any errors that occurred for the failed command.

Nontransactional

If the **Transaction** attribute is set to false, the **Batch** command runs each command contained by the **Batch** command in a separate transaction-a *nontransactional* batch. If any command fails in a nontransactional batch, the **Batch** command continues to run commands after the command which failed. After the **Batch** command tries to run all the commands that the **Batch** command contains, the **Batch** command reports any errors that occurred.

All results returned by commands contained in a **Batch** command are returned in the same order in which the commands are contained in the **Batch** command. The results returned by a **Batch** command vary based on whether the **Batch** command is transactional or nontransactional.

① Note

If a **Batch** command contains a command that does not return output, such as the [Lock](#) command, and that command successfully runs, the **Batch** command returns an empty **root** element within the results element. The empty **root** element ensures that each command contained in a **Batch** command can be matched with the appropriate **root** element for that command's results.

Returning Results from Transactional Batch Results

Results from commands run within a transactional batch are not returned until the entire **Batch** command is completed. The results are not returned after each command runs because any command that fails within a transactional batch would cause the entire **Batch** command and all containing commands to be rolled back. If all commands start and run successfully, the [return](#) element of the [ExecuteResponse](#) element returned by the [Execute](#) method for the **Batch** command contains one [results](#) element, which in turn contains one **root** element for each successfully run command contained in the **Batch** command. If any command in the **Batch** command cannot be started or fails to complete, the [Execute](#) method returns a SOAP fault for the **Batch** command that contains the error of the command that failed.

Returning Results from Nontransactional Batch Results

Results from commands run within a nontransactional batch are returned in the order in which the commands are contained within the **Batch** command and as they are returned by each command. If no command contained in the **Batch** command can be successfully started, the [Execute](#) method returns a SOAP fault that contains an error for the **Batch** command. If at least one command is successfully started, the [return](#) element of the [ExecuteResponse](#) element returned by the [Execute](#) method for the **Batch** command contains one [results](#) element, which in turn contains one **root** element for each command contained in the **Batch** command. If one or more commands in a nontransactional batch cannot be started or fails to complete, the **root** element for that failed command contains an [error](#) element describing the error.

Note

As long as at least one command in a nontransactional batch can be started, the nontransactional batch is considered to have successfully run, even if every command contained in the nontransactional batch returns an error in the results of the **Batch** command.

Using Serial and Parallel Execution

You can use the **Batch** command to run included commands in serial or in parallel. When the commands are run in serial, the next command included in the **Batch** command cannot start until the currently running command in the **Batch** command is completed. When the commands are run in parallel, multiple commands can be executed simultaneously by the **Batch** command.

To run commands in parallel, you add the commands to be run in parallel to the **Parallel** property of the **Batch** command. Currently, SQL Server Analysis Services can run only contiguous, sequential **Process** commands in parallel. Any other XMLA command, such as **Create** or **Alter**, included in the **Parallel** property is run serially.

SQL Server Analysis Services tries to run all **Process** commands included in the **Parallel** property in parallel, but cannot guarantee that all included **Process** commands can be run in parallel. The instance analyzes each **Process** command and, if the instance determines that the command cannot be run in parallel, the **Process** command is run in serial.

ⓘ Note

To run commands in parallel, the **Transaction** attribute of the **Batch** command must be set to true because SQL Server Analysis Services supports only one active transaction per connection and nontransactional batches run each command in a separate transaction. If you include the **Parallel** property in a nontransactional batch, an error occurs.

Limiting Parallel Execution

An SQL Server Analysis Services instance tries to run as many **Process** commands in parallel as possible, up to the limits of the computer on which the instance runs. You can limit the number of concurrently executing **Process** commands by setting the **maxParallel** attribute of the **Parallel** property to a value indicating the maximum number of **Process** commands that can be run in parallel.

For example, a **Parallel** property contains the following commands in the sequence listed:

1. **Create**
2. **Process**

3. Alter

4. Process

5. Process

6. Process

7. Delete

8. Process

9. Process

The **maxParallel** attribute of this **Parallel** property is set to 2. Therefore, the instance runs the previous lists of commands as described in the following list:

- Command 1 runs serially because command 1 is a **Create** command and only **Process** commands can be run in parallel.
- Command 2 runs serially after command 1 is completed.
- Command 3 runs serially after command 2 is completed.
- Commands 4 and 5 run in parallel after command 3 is completed. Although command 6 is also a **Process** command, command 6 cannot run in parallel with commands 4 and 5 because the **maxParallel** property is set to 2.
- Command 6 runs serially after both commands 4 and 5 are completed.
- Command 7 runs serially after command 6 is completed.
- Commands 8 and 9 run in parallel after command 7 is completed.

Using the Batch Command to Process Objects

The **Batch** command contains several optional properties and attributes specifically included to support processing multiple SQL Server Analysis Services projects:

- The **ProcessAffectedObjects** attribute of the **Batch** command indicates whether the instance should also process any object that requires reprocessing as a result of a **Process** command included in the **Batch** command processing a specified object.
- The **Bindings** property contains a collection of out-of-line bindings used by all of the **Process** commands in the **Batch** command.

- The [DataSource](#) property contains an out-of-line binding for a data source used by all of the **Process** commands in the **Batch** command.
- The [DataSourceView](#) property contains an out-of-line binding for a data source view used by all of the **Process** commands in the **Batch** command.
- The [ErrorConfiguration](#) property specifies the way in which the **Batch** command handles errors encountered by all **Process** commands contained in the **Batch** command.

 **Important**

A **Process** command cannot include the **Bindings**, **DataSource**, **DataSourceView**, or **ErrorConfiguration** properties, if the **Process** command is contained in a **Batch** command. If you must specify these properties for a **Process** command, provide the necessary information in the corresponding properties of the **Batch** command that contains the **Process** command.

Processing Objects (XMLA)

Article • 12/09/2022

In Microsoft SQL Server SQL Server Analysis Services, processing is the step or series of steps that turn data into information for business analysis. Processing is different depending on the type of object, but processing is always part of turning data into information.

To process an SQL Server Analysis Services object, you can use the [Process](#) command. The **Process** command can process the following objects on an SQL Server Analysis Services instance:

- Cubes
- Databases
- Dimensions
- Measure groups
- Mining models
- Mining structures
- Partitions

To control the processing of objects, the **Process** command has various properties that can be set. The **Process** command has properties that control: how much processing will be done, which objects will be processed, whether to use out-of-line bindings, how to handle errors, and how to manage writeback tables.

Specifying Processing Options

The [Type](#) property of the **Process** command specifies the processing option to use when processing the object. For more information about processing options, see [Processing Options and Settings \(Analysis Services\)](#).

The following table lists the constants for the **Type** property and the various objects that can be processed using each constant.

 Expand table

Type value	Applicable objects
<i>ProcessFull</i>	Cube, database, dimension, measure group, mining model, mining structure, partition
<i>ProcessAdd</i>	Dimension, partition
<i>ProcessUpdate</i>	Dimension
<i>ProcessIndexes</i>	Dimension, cube, measure group, partition
<i>ProcessData</i>	Dimension, cube, measure group, partition
<i>ProcessDefault</i>	Cube, database, dimension, measure group, mining model, mining structure, partition
<i>ProcessClear</i>	Cube, database, dimension, measure group, mining model, mining structure, partition
<i>ProcessStructure</i>	Cube, mining structure
<i>ProcessClearStructureOnly</i>	Mining structure
<i>ProcessScriptCache</i>	Cube

For more information about processing SQL Server Analysis Services objects, see [Processing a multidimensional model \(Analysis Services\)](#).

Specifying Objects to be Processed

The **Object** property of the **Process** command contains the object identifier of the object to be processed. Only one object can be specified in a **Process** command, but processing an object also processes any child objects. For example, processing a measure group in a cube processes all the partitions for that measure group, while processing a database processes all the objects, including cubes, dimensions, and mining structures, that are contained by the database.

If you set the **ProcessAffectedObjects** attribute of the **Process** command to true, any related object affected by processing the specified object is also processed. For example, if a dimension is incrementally updated by using the *ProcessUpdate* processing option in the **Process** command, any partition whose aggregations are invalidated because of members being added or deleted is also processed by SQL Server Analysis Services if **ProcessAffectedObjects** is set to true. In this case, a single **Process** command can process multiple objects on an SQL Server Analysis Services instance, but SQL Server Analysis Services determines which objects besides the single object specified in the **Process** command must also be processed.

However, you can process multiple objects, such as dimensions, at the same time by using multiple **Process** commands within a **Batch** command. Batch operations provide a finer level of control for serial or parallel processing of objects on an SQL Server Analysis Services instance than using the **ProcessAffectedObjects** attribute, and let you to tune your processing approach for larger SQL Server Analysis Services databases. For more information about performing batch operations, see [Performing Batch Operations \(XMLA\)](#).

Specifying Out-of-Line Bindings

If the **Process** command is not contained by a **Batch** command, you can optionally specify out-of-line bindings in the **Bindings**, **DataSource**, and **DataSourceView** properties of the **Process** command for the objects to be processed. Out-of-line bindings are references to data sources, data source views, and other objects in which the binding exists only during the execution of the **Process** command, and which override any existing bindings associated with the objects being processed. If out-of-line bindings are not specified, the bindings currently associated with the objects to be processed are used.

Out-of-line bindings are used in the following circumstances:

- Incrementally processing a partition, in which an alternative fact table or a filter on the existing fact table must be specified to make sure that rows are not counted twice.
- Using a data flow task in Microsoft SQL Server Integration Services to provide data while processing a dimension, mining model, or partition.

Out-of-line bindings are described as part of the Analysis Services Scripting Language (ASSL). For more information about out-of-line bindings in ASSL, see [Data Sources and Bindings \(SSAS Multidimensional\)](#).

Incrementally Updating Partitions

Incrementally updating an already processed partition typically requires an out-of-line binding because the binding specified for the partition references fact table data already aggregated within the partition. When incrementally updating an already processed partition by using the **Process** command, SQL Server Analysis Services performs the following actions:

- Creates a temporary partition with a structure identical to that of the partition to be incrementally updated.

- Processes the temporary partition, using the out-of-line binding specified in the **Process** command.
- Merges the temporary partition with the existing selected partition.

For more information about merging partitions using XML for Analysis (XMLA), see [Merging Partitions \(XMLA\)](#).

Handling Processing Errors

The **ErrorConfiguration** property of the **Process** command lets you specify how to handle errors encountered while processing an object. For example, while processing a dimension, SQL Server Analysis Services encounters a duplicate value in the key column of the key attribute. Because attribute keys must be unique, SQL Server Analysis Services discards the duplicate records. Based on the **KeyDuplicate** property of **ErrorConfiguration**, SQL Server Analysis Services could:

- Ignore the error and continue processing the dimension.
- Return a message that states SQL Server Analysis Services encountered a duplicate key and continue processing.

There are many similar conditions for which **ErrorConfiguration** provides options during a **Process** command.

Managing Writeback Tables

If the **Process** command encounters a write-enabled partition, or a cube or measure group for such a partition, that is not already fully processed, a writeback table may not already exist for that partition. The **WritebackTableCreation** property of the **Process** command determines whether SQL Server Analysis Services should create a writeback table.

Examples

Description

The following example fully processes the Adventure Works DW Multidimensional 2012 sample SQL Server Analysis Services database.

Code

```

<Process xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Object>
    <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
  </Object>
  <Type>ProcessFull</Type>
  <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
</Process>

```

Description

The following example incrementally processes the **Internet_Sales_2004** partition in the **Internet Sales** measure group of the **Adventure Works DW** cube in the Adventure Works DW Multidimensional 2012 sample SQL Server Analysis Services database. The **Process** command is adding aggregations for order dates later than December 31, 2006 to the partition by using an out-of-line query binding in the **Bindings** property of the **Process** command to retrieve the fact table rows from which to generate aggregations to add to the partition.

Code

```

<Process ProcessAffectedObjects="true"
  xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
  <Object>
    <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
    <CubeID>Adventure Works DW</CubeID>
    <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
    <PartitionID>Internet_Sales_2006</PartitionID>
  </Object>
  <Bindings>
    <Binding>
      <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>
      <CubeID>Adventure Works DW</CubeID>
      <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
      <PartitionID>Internet_Sales_2006</PartitionID>
      <Source xmlns:xsd="http://www.w3.org/2001/XMLSchema"
        xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:type="QueryBinding">
        <DataSourceID>Adventure Works DW</DataSourceID>
        <QueryDefinition>
          SELECT
            [dbo].[FactInternetSales].[ProductKey],
            [dbo].[FactInternetSales].[OrderDateKey],
            [dbo].[FactInternetSales].[DueDateKey],
            [dbo].[FactInternetSales].[ShipDateKey],

```

```
[dbo].[FactInternetSales].[CustomerKey],  
[dbo].[FactInternetSales].[PromotionKey],  
[dbo].[FactInternetSales].[CurrencyKey],  
[dbo].[FactInternetSales].[SalesTerritoryKey],  
[dbo].[FactInternetSales].[SalesOrderNumber],  
[dbo].[FactInternetSales].[SalesOrderLineNumber],  
[dbo].[FactInternetSales].[RevisionNumber],  
[dbo].[FactInternetSales].[OrderQuantity],  
[dbo].[FactInternetSales].[UnitPrice],  
[dbo].[FactInternetSales].[ExtendedAmount],  
[dbo].[FactInternetSales].[UnitPriceDiscountPct],  
[dbo].[FactInternetSales].[DiscountAmount],  
[dbo].[FactInternetSales].[ProductStandardCost],  
[dbo].[FactInternetSales].[TotalProductCost],  
[dbo].[FactInternetSales].[SalesAmount],  
[dbo].[FactInternetSales].[TaxAmt],  
[dbo].[FactInternetSales].[Freight],  
[dbo].[FactInternetSales].[CarrierTrackingNumber],  
[dbo].[FactInternetSales].[CustomerPONumber]  
FROM [dbo].[FactInternetSales]  
WHERE OrderDateKey > '1280'  
</QueryDefinition>  
</Source>  
</Binding>  
</Bindings>  
<Type>ProcessAdd</Type>  
<WriteBackTableCreation>UseExisting</WriteBackTableCreation>  
</Process>
```

Updating Cells (XMLA)

Article • 12/09/2022

You can use the [UpdateCells](#) command to change the value of one or more cells in a cube enabled for cube writeback. Microsoft SQL Server SQL Server Analysis Services stores the updated information in a separate writeback table for each partition that contains cells to be updated.

ⓘ Note

The [UpdateCells](#) command does not support allocations during cube writeback. To use allocated writeback, you should use the [Statement](#) command to send a Multidimensional Expressions (MDX) UPDATE statement. For more information, see [UPDATE CUBE Statement \(MDX\)](#).

Specifying Cells

The [Cell](#) property of the [UpdateCells](#) command contains the cells to be updated. You identify each cell in the [Cell](#) property using that cell's ordinal number. Conceptually, SQL Server Analysis Services numbers cells in a cube as if the cube were a p -dimensional array, where p is the number of axes. Cells are addressed in row-major order. The following illustration shows the formula for calculating the ordinal number of a cell.

If axis k has U_k members, the ordinal number of a cell whose tuple ordinals are $(S_0, S_1, S_2, \dots, S_{p-1})$ is

$$\sum_{i=0}^{p-1} S_i \times E_i \text{, where } E_0 = 1 \text{ and } E_i = \prod_{k=0}^{i-1} U_k$$

Σ represents the sum of the terms in the series and Π the product.

Once you know a cell's ordinal number, you can indicate the intended value of the cell in the [Value](#) property of the [Cell](#) property.

ASSL XML Conventions

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Analysis Services Scripting Language (ASSL) represents the hierarchy of objects as a set of element types, each of which defines the child elements they can contain.

To represent the object hierarchy, ASSL uses the following XML conventions:

- All objects and properties are represented as elements, except for standard XML attributes such as 'xml:lang'.
- Both element names and enumeration values follow the Microsoft .NET Framework naming convention of Pascal casing with no underscores.
- The case of all values is preserved. Values for enumerations are also case-sensitive.

In addition to this list of conventions, Analysis Services also follows certain conventions regarding cardinality, inheritance, whitespace, data types, and default values.

Cardinality

When an element has a cardinality that is greater than 1, there is an XML element collection that encapsulates this element. The name of collection uses the plural form of the elements contained in the collection. For example, the following XML fragment represents the **Dimensions** collection within a **Database** element:

```
<Database>
...
<Dimensions>
  <Dimension>
    ...
  </Dimension>
  <Dimension>
    ...
  </Dimension>
...

```

```
</Dimension>
```

```
</Dimensions>
```

```
</Database>
```

```
--
```

The order in which elements appear is unimportant.

Inheritance

Inheritance is used when there are distinct objects that have overlapping but significantly different sets of properties. Examples of such overlapping but distinct objects are virtual cubes, linked cubes, and regular cubes. For overlapping but distinct object, Analysis Services uses the standard **type** attribute from the XML Instance Namespace to indicate the inheritance. For example, the following XML fragment shows how the **type** attribute identifies whether a **Cube** element inherits from a regular cube or from a virtual cube:

```
<Cubes>
```

```
<Cube xsi:type="RegularCube">
```

```
<Name>Sales</Name>
```

```
...
```

```
</Cube>
```

```
<Cube xsi:type="VirtualCube">
```

```
<Name>SalesAndInventory</Name>
```

```
...
```

```
</Cube>
```

```
</Cubes>
```

```
--
```

Inheritance is generally not used when multiple types have a property of the same name. For example, the **Name** and **ID** properties appear on many elements, but these properties have not been promoted to an abstract type.

Whitespace

Whitespace within an element value is preserved. However, leading and trailing whitespace is always trimmed. For example, the following elements have the same text but differing amounts of whitespace within that text, and are therefore treated as if they have different values:

```
<Description>My text<Description>
```

```
<Description>My text<Description>
```

..

However, the following elements vary only in leading and trailing whitespace, and are therefore treated as if they have equivalent values:

```
<Description>My text<Description>
```

```
<Description> My text <Description>
```

..

Data Types

Analysis Services uses the following standard XML Schema definition language (XSD) data types:

Int

An integer value in the range of -2³¹ to 2³¹ - 1.

Long

An integer value in range of -2⁶³ to 2⁶³ - 1.

String

A string value that conforms to the following global rules:

- Control characters are stripped out.
- Leading and trailing white space is trimmed.
- Internal white space is preserved.

Name and **ID** properties have special limitations on valid characters in string elements. For additional information about **Name** and **ID** conventions, see [ASSL Objects and Object Characteristics](#).

DateTime

A **DateTime** structure from the .NET Framework. A **DateTime** value cannot be NULL. The lowest date supported by the **DateTime** data type is January 1, 1601, which is available to programmers as **DateTime.MinValue**. The lowest supported date indicates that a **DateTime** value is missing.

Boolean

An enumeration with only two values, such as {true, false} or {0, 1}.

Default Values

Analysis Services uses the defaults listed in the following table.

 Expand table

XML data type	Default value
Boolean	False
String	"" (empty string)
Integer or Long	0 (zero)
Timestamp	12:00:00 AM, 1/1/0001 (corresponding to a the .NET Frameworks System.DateTime with 0 ticks)

An element that is present but empty is interpreted as having a value of a null string, not the default value.

Inherited Defaults

Some properties that are specified on an object provide default values for the same property on child or descendant objects. For example, **Cube.StorageMode** provides the default value for **Partition.StorageMode**. The rules that Analysis Services applies for inherited default values are as follows:

- When the property for the child object is null in the XML, its value defaults to the inherited value. However, if you query the value from the server, the server returns the null value of the XML element.
- It is not possible to determine programmatically whether the property of a child object has been set directly on the child object or inherited.

Some elements have defined defaults that apply when the element is missing. For example, the **Dimension** elements in the following XML fragment are equivalent even though one **Dimension** element contains a **Visible** element, but the other **Dimension** element does not.

```
<Dimension>  
  <Name>Product</Name>  
  </Dimension>  
  
<Dimension>  
  <Name>Product</Name>  
  <Visible>true</Visible>  
  </Dimension>
```

For more information on inherited defaults, see [ASSL Objects and Object Characteristics](#).

Database Objects (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A Microsoft SQL Server SQL Server Analysis Services instance contains database objects and assemblies for use with online analytical processing (OLAP) and data mining.

- Databases contain OLAP and data mining objects, such as data sources, data source views, cubes, measures, measure groups, dimensions, attributes, hierarchies, mining structures, mining models and roles.
- Assemblies contain user-defined functions that extend the functionality of the intrinsic functions provided with the Multidimensional Expressions (MDX) and Data Mining Extensions (DMX) languages.

The [Database](#) object is the container for all data objects that are needed for a business intelligence project (such as OLAP cubes, dimensions, and data mining structures), and their supporting objects (such as [DataSource](#), [Account](#), and [Role](#)).

A [Database](#) object provides access to objects and attributes that include the following:

- All cubes that you can access, as a collection.
- All dimensions that you can access, as a collection.
- All mining structures that you can access, as a collection.
- All data sources and data source views, as two collections.
- All roles and database permissions, as two collections.
- The collation value for the database.
- The estimated size of the database.
- The language value of the database.
- The visible setting for the database.

In This Section

The following topics describe objects shared by both OLAP and data mining features in SQL Server Analysis Services.

 Expand table

Topic	Description
Data Sources in Multidimensional Models	Describes a data source in SQL Server Analysis Services.
Data Source Views in Multidimensional Models	Describes a logical data model based on one or more data sources, in SQL Server Analysis Services.
Cubes in Multidimensional Models	Describes cubes and cube objects, including measures, measure groups, dimension usage relationships, calculations, key performance indicators, actions, translations, partitions, and perspectives.
Dimensions (Analysis Services - Multidimensional Data)	Describes dimensions and dimension objects, including attributes, attribute relationships, hierarchies, levels, and members.
Mining Structures (Analysis Services - Data Mining)	Describes mining structures and mining objects, including mining models.
Security Roles (Analysis Services - Multidimensional Data)	Describes a role, the security mechanism used to control access to objects in SQL Server Analysis Services.
Multidimensional Model Assemblies Management	Describes an assembly, a collection of user-defined functions used to extend the MDX and DMX languages, in SQL Server Analysis Services.

Attribute Relationships

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

In Microsoft SQL Server SQL Server Analysis Services, attributes within a dimension are always related either directly or indirectly to the key attribute. When you define a dimension based on a star schema, which is where all dimension attributes are derived from the same relational table, an attribute relationship is automatically defined between the key attribute and each non-key attribute of the dimension. When you define a dimension based on a snowflake schema, which is where dimension attributes are derived from multiple related tables, an attribute relationship is automatically defined as follows:

- Between the key attribute and each non-key attribute bound to columns in the main dimension table.
- Between the key attribute and the attribute bound to the foreign key in the secondary table that links the underlying dimension tables.
- Between the attribute bound to foreign key in the secondary table and each non-key attribute bound to columns from the secondary table.

However, there are a number of reasons why you might want to change these default attribute relationships. For example, you might want to define a natural hierarchy, a custom sort order, or dimension granularity based on a non-key attribute. For more information, see [Dimension Attribute Properties Reference](#).

Note

Attribute relationships are known in Multidimensional Expressions (MDX) as member properties.

Natural Hierarchy Relationships

A hierarchy is a natural hierarchy when each attribute included in the user-defined hierarchy has a one to many relationship with the attribute immediately below it. For example, consider a Customer dimension based on a relational source table with eight columns:

- CustomerKey
- CustomerName
- Age
- Gender
- Email
- City
- Country
- Region

The corresponding Analysis Services dimension has seven attributes:

- Customer (based on CustomerKey, with CustomerName supplying member names)
- Age, Gender, Email, City, Region, Country

Relationships representing natural hierarchies are enforced by creating an attribute relationship between the attribute for a level and the attribute for the level below it. For SQL Server Analysis Services, this specifies a natural relationship and potential aggregation. In the Customer dimension, a natural hierarchy exists for the Country, Region, City, and Customer attributes. The natural hierarchy for `{Country, Region, City, Customer}` is described by adding the following attribute relationships:

- The Country attribute as an attribute relationship to the Region attribute.
- The Region attribute as an attribute relationship to the City attribute.
- The City attribute as an attribute relationship to the Customer attribute.

For navigating data in the cube, you can also create a user-defined hierarchy that does not represent a natural hierarchy in the data (which is called an *ad hoc or reporting* hierarchy). For example, you could create a user-defined hierarchy based on `{Age, Gender}`. Users do not see any difference in how the two hierarchies behave, although the natural hierarchy benefits from aggregating and indexing structures - hidden from the user - that account for the natural relationships in the source data.

The **SourceAttribute** property of a level determines which attribute is used to describe the level. The **KeyColumns** property on the attribute specifies the column in the data source view that supplies the members. The **NameColumn** property on the attribute can specify a different name column for the members.

To define a level in a user-defined hierarchy using SQL Server Data Tools, the **Dimension Designer** allows you to select a dimension attribute, a column in a dimension table, or a column from a related table included in the data source view for the cube. For more information about creating user-defined hierarchies, see [Create User-Defined Hierarchies](#).

In Analysis Services, an assumption is usually made about the content of members. Leaf members have no descendants and contain data derived from underlying data sources. Nonleaf members have descendants and contain data derived from aggregations performed on child members. In aggregated levels, members are based on aggregations of subordinate levels. Therefore, when the **IsAggregatable** property is set to **False** on a source attribute for a level, no aggregatable attributes should be added as levels above it.

Defining an Attribute Relationship

The main constraint when you create an attribute relationship is to make sure that the attribute referred to by the attribute relationship has no more than one value for any member in the attribute to which the attribute relationship belongs. For example, if you define a relationship between a City attribute and a State attribute, each city can only relate to a single state.

Attribute Relationship Queries

You can use MDX queries to retrieve data from attribute relationships, in the form of member properties, with the **PROPERTIES** keyword of the MDX **SELECT** statement. For more information about how to use MDX to retrieve member properties, see [Using Member Properties \(MDX\)](#).

Attributes and Attribute Hierarchies

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Dimensions are collections of attributes, which are bound to one or more columns in a table or view in the data source view.

Key Attribute

Each dimension contains a key attribute. Each attribute is bound to one or more columns in a dimension table. The key attribute is the attribute in a dimension that identifies the columns in the dimension main table that are used in foreign key relationships to the fact table. Typically, the key attribute represents the primary key column or columns in the dimension table. You can define a logical primary key on a table in a data source view which has no physical primary key in the underlying data source. [For more information](#), see [Define Logical Primary Keys in a Data Source View \(Analysis Services\)](#). When defining key attributes, the Cube Wizard and Dimension Wizard try to use the primary key columns of the dimension table in the data source view. If the dimension table does not have a logical primary key or physical primary key defined, the wizards may not be able to correctly define the key attributes for the dimension.

Binding an Attribute to Columns in Data Source View Tables or Views

An attribute is bound to columns in one or more data source view tables or views. An attribute is always bound to one or more key columns, which determines the members that are contained by the attribute. By default, this is the only column to which an attribute is bound. An attribute can also be bound to one or more additional columns for specific purposes. For example, an attribute's **NameColumn** property determines the name that appears to the user for each attribute member - this property of the attribute can be bound to a particular dimension column through a data source view or can be bound to a calculated column in the data source view. For more information, see [Dimension Attribute Properties Reference](#).

Attribute Hierarchies

By default, attribute members are organized into two level hierarchies, consisting of a leaf level and an All level. The All level contains the aggregated value of the attribute's members across the measures in each measure group to which the dimension of which the attribute is related is a member. However, if the **IsAggregatable** property is set to False, the All level is not created. For more information, see [Dimension Attribute Properties Reference](#).

Attributes can be, and typically are, arranged into user-defined hierarchies that provide the drill-down paths by which users can browse the data in the measure groups to which the attribute is related. In client applications, attributes can be used to provide grouping and constraint information. When attributes are arranged into user-defined hierarchies, you define relationships between hierarchy levels when levels are related in a many-to-one or a one-to-one relationship (called a *natural* relationship). For example, in a Calendar Time hierarchy, a Day level should be related to the Month level, the Month level related to the Quarter level, and so on. Defining relationships between levels in a user-defined hierarchy enables Analysis Services to define more useful aggregations to increase query performance and can also save memory during processing performance, which can be important with large or complex cubes. For more information, see [User Hierarchies](#), [Create User-Defined Hierarchies](#), and [Define Attribute Relationships](#).

Attribute Relationships, Star Schemas, and Snowflake Schemas

By default, in a star schema, all attributes are directly related to the key attribute, which enables users to browse the facts in the cube based on any attribute hierarchy in the dimension. In a snowflake schema, an attribute is either directly linked to the key attribute if their underlying table is directly linked to the fact table or is indirectly linked by means of the attribute that is bound to the key in the underlying table that links the snowflake table to the directly linked table.

Database Dimension Properties - Types

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The **Type** property setting provides information about the contents of a dimension to server and client applications. In some cases, the **Type** setting only provides guidance for client applications and is optional. In other cases, such as **Accounts** or **Time** dimensions, the **Type** property settings for the dimension and its attributes determine specific server-based behaviors and may be required to implement certain behaviors in the cube. For example, the **Type** property of a dimension can be set to **Accounts** to indicate to client applications that the standard dimension contains account attributes. For more information about time, account, and currency dimensions, see [Create a Date type Dimension](#), [Create a Finance Account of parent-child type Dimension](#), and [Create a Currency type Dimension](#).

The default setting for the dimension type is **Regular**, which makes no assumptions about the contents of the dimension. This is the default setting for all dimensions when you initially define a dimension unless you specify **Time** when defining the dimension using the Dimension Wizard. You should also leave **Regular** as the dimension type if the Dimension Wizard does not list an appropriate type for Dimension type.

Available Dimension Types

The following table describes the dimension types available in Microsoft SQL Server SQL Server Analysis Services.

 [Expand table](#)

Dimension type	Description
Regular	A dimension whose type has not been set to a special dimension type.
Time	A dimension whose attributes represent time periods, such as years, semesters, quarters, months, and days.
Organization	A dimension whose attributes represent organizational information, such as employees or subsidiaries.
Geography	A dimension whose attributes represent geographic information, such as cities or postal codes.

Dimension type	Description
BillOfMaterials	A dimension whose attributes represent inventory or manufacturing information, such as parts lists for products.
Accounts	A dimension whose attributes represent a chart of accounts for financial reporting purposes.
Customers	A dimension whose attributes represent customer or contact information.
Products	A dimension whose attributes represent product information.
Scenario	A dimension whose attributes represent planning or strategic analysis information.
Quantitative	A dimension whose attributes represent quantitative information.
Utility	A dimension whose attributes represent miscellaneous information.
Currency	This type of dimension contains currency data and metadata.
Rates	A dimension whose attributes represent currency rate information.
Channel	A dimension whose attributes represent channel information.
Promotion	A dimension whose attributes represent marketing promotion information.

Database Dimension Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

In Microsoft SQL Server SQL Server Analysis Services, the characteristics of a dimension are defined by the metadata for the dimension, based on the settings of various dimension properties, and on the attributes or hierarchies that are contained by the dimension. The following table describes the dimension properties in SQL Server Analysis Services.

 Expand table

Property	Description
AttributeAllMemberName	Specifies the name of the All member for attributes in a dimension.
Collation	Determines the collation used by the dimension.
CurrentStorageMode	Contains the current storage mode for the dimension.
DependsOnDimension	Contains the ID of another dimension on which the dimension depends, if any.
Description	Contains the description of the dimension.
ErrorConfiguration	Configurable error handling settings for handling of duplicate keys, unknown keys, error limits, action upon error detection, error log file, and null key handling.
ID	Contains the unique identifier (ID) of the dimension.
Language	Specifies the default language for the dimension.
MdxMissingMemberMode	Determines how missing members are handled for Multidimensional Expressions (MDX) statements.
MiningModelID	Contains the ID of the mining model with which the data mining dimension is associated. This property is applicable only if the dimension is a mining model dimension.
Name	Specifies the name of the dimension.
ProactiveCaching	Defines the proactive cache settings for the dimension.
ProcessingGroup	Specifies the processing group. Values are ByAttribute or ByTable. Default is ByAttribute .

Property	Description
ProcessingMode	Indicates whether SQL Server Analysis Services should index and aggregate during or after processing.
ProcessingPriority	Determines the processing priority of the dimension during background operations such as lazy aggregation, indexing, or clustering.
Source	Identifies the data source view to which the dimension is bound.
StorageMode	Determines the storage mode for the dimension.
Type	Specifies the type of the dimension.
UnknownMember	Indicates whether the unknown member is visible.
UnknownMemberName	Specifies the caption, in the default language of the dimension, for the unknown member of the dimension.
WriteEnabled	Indicates whether dimension writebacks are available (subject to security permissions).

 **Note**

For more information about setting values for the ErrorConfiguration and UnknownMember properties when working with null values and other data integrity issues, see [Handling Data Integrity Issues in Analysis Services 2005](#).

Dimension Objects (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A simple [Dimension](#) object is composed of basic information, attributes, and hierarchies. Basic information includes the name of the dimension, the type of the dimension, the data source, the storage mode, and others. Attributes define the actual data in the dimension. Attributes do not necessarily belong to a hierarchy, but hierarchies are built from attributes. A hierarchy creates ordered lists of levels, and defines the ways a user can explore the dimension.

In This Section

The following topics provide more information about how to design and implement dimension objects.

 Expand table

Topic	Description
Dimensions (Analysis Services - Multidimensional Data)	In Microsoft SQL Server SQL Server Analysis Services, dimensions are a fundamental component of cubes. Dimensions organize data with relation to an area of interest, such as customers, stores, or employees, to users.
Attributes and Attribute Hierarchies	Dimensions are collections of attributes, which are bound to one or more columns in a table or view in the data source view.
Attribute Relationships	In Microsoft SQL Server SQL Server Analysis Services, attributes within a dimension are always related either directly or indirectly to the key attribute. When you define a dimension based on a star schema, which is where all dimension attributes are derived from the same relational table, an attribute relationship is automatically defined between the key attribute and each non-key attribute of the dimension. When you define a dimension based on a snowflake schema, which is where dimension attributes are derived from multiple related tables, an attribute relationship is automatically defined as follows: Between the key attribute and each non-key attribute bound to columns in the main dimension table.

Topic	Description
	Between the key attribute and the attribute bound to the foreign key in the secondary table that links the underlying dimension tables.
	Between the attribute bound to foreign key in the secondary table and each non-key attribute bound to columns from the secondary table.

Dimension Translations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A translation is a simple mechanism to change the displayed labels and captions from one language to another. Each translation is defined as a pair of values: a string with the translated text, and a number with the language ID. Translations are available for all objects in SQL Server Analysis Services. Dimensions can also have the attribute values translated. The client application is responsible for finding the language setting that the user has defined, and switch to display all captions and labels to that language. An object can have as many translations as you want.

A simple [Translation](#) object is composed of: language ID number, and translated caption. The language ID number is an [Integer](#) with the language ID. The translated caption is the translated text.

In Microsoft SQL Server SQL Server Analysis Services, a dimension translation is a language-specific representation of the name of a dimension, the name of an SQL Server Analysis Services object or one of its members, such as a caption, member, or hierarchy level. SQL Server SQL Server Analysis Services also supports translations of cube objects.

Translations provide server support for client applications that can support multiple languages. Frequently, users from different countries/regions view a cube and its dimensions. It is useful to be able to translate various elements of a cube and its dimensions into a different language so that these users can view and understand the cube. For example, a business user in France can access a cube from a workstation with a French locale setting, and see the object property values in French. However, a business user in Germany who accesses the same cube from a workstation with a German locale setting sees the same object property values in German.

The collation and language information for the client computer is stored in the form of a locale identifier (LCID). Upon connection, the client passes the LCID to the instance of SQL Server Analysis Services. The instance uses the LCID to determine which set of translations to use when providing metadata for SQL Server Analysis Services objects. If an SQL Server Analysis Services object does not contain the specified translation, the default language is used to return the content back to the client.

Dimensions - Introduction

Article • 12/09/2022

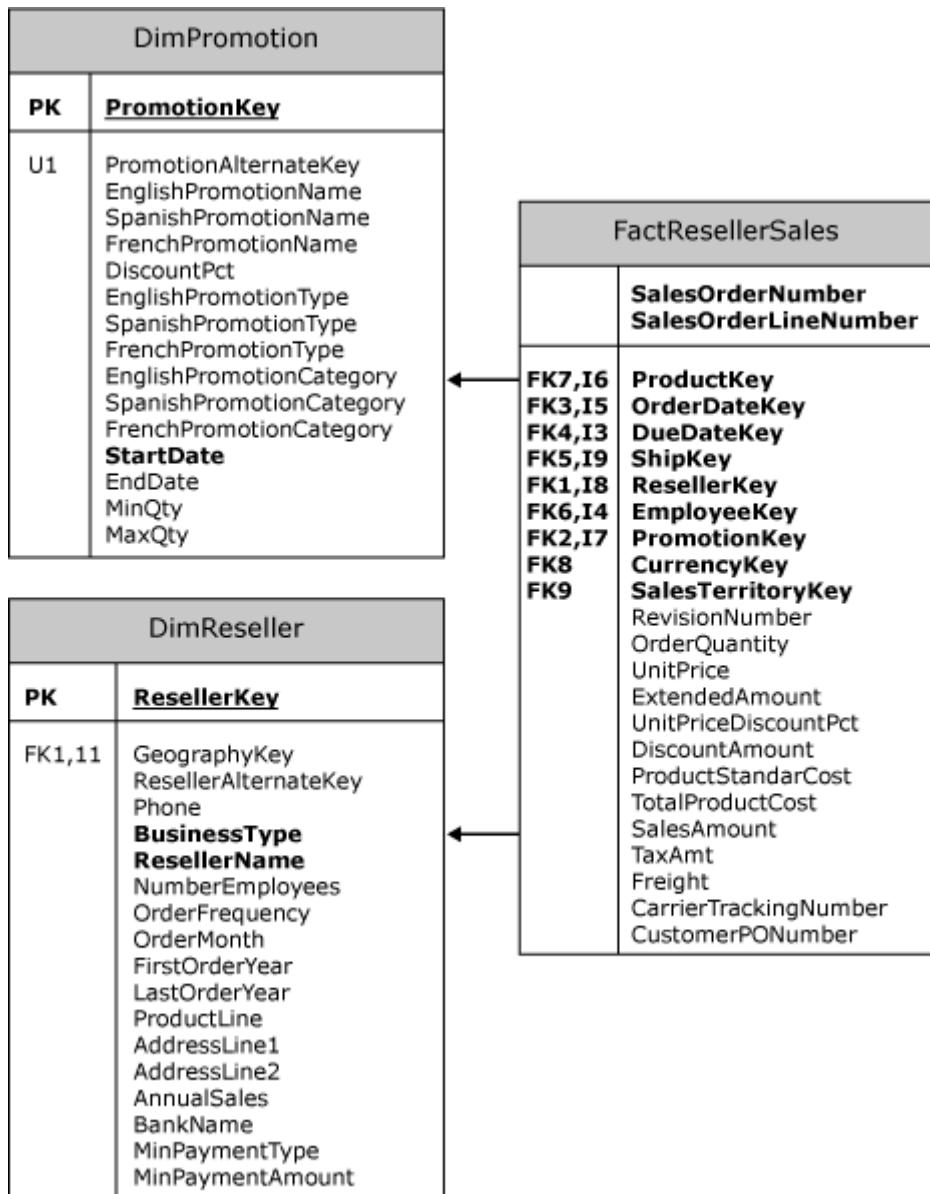

Applies to: ✓ SQL Server Analysis Services ✖ Azure Analysis Services ✖
Fabric/Power BI Premium

All Microsoft SQL Server SQL Server Analysis Services dimensions are groups of attributes based on columns from tables or views in a data source view. Dimensions exist independent of a cube, can be used in multiple cubes, can be used multiple times in a single cube, and can be linked between SQL Server Analysis Services instances. A dimension that exists independent of a cube is called a database dimension and an instance of a database dimension within a cube is called a cube dimension.

Dimension based on a Star Schema Design

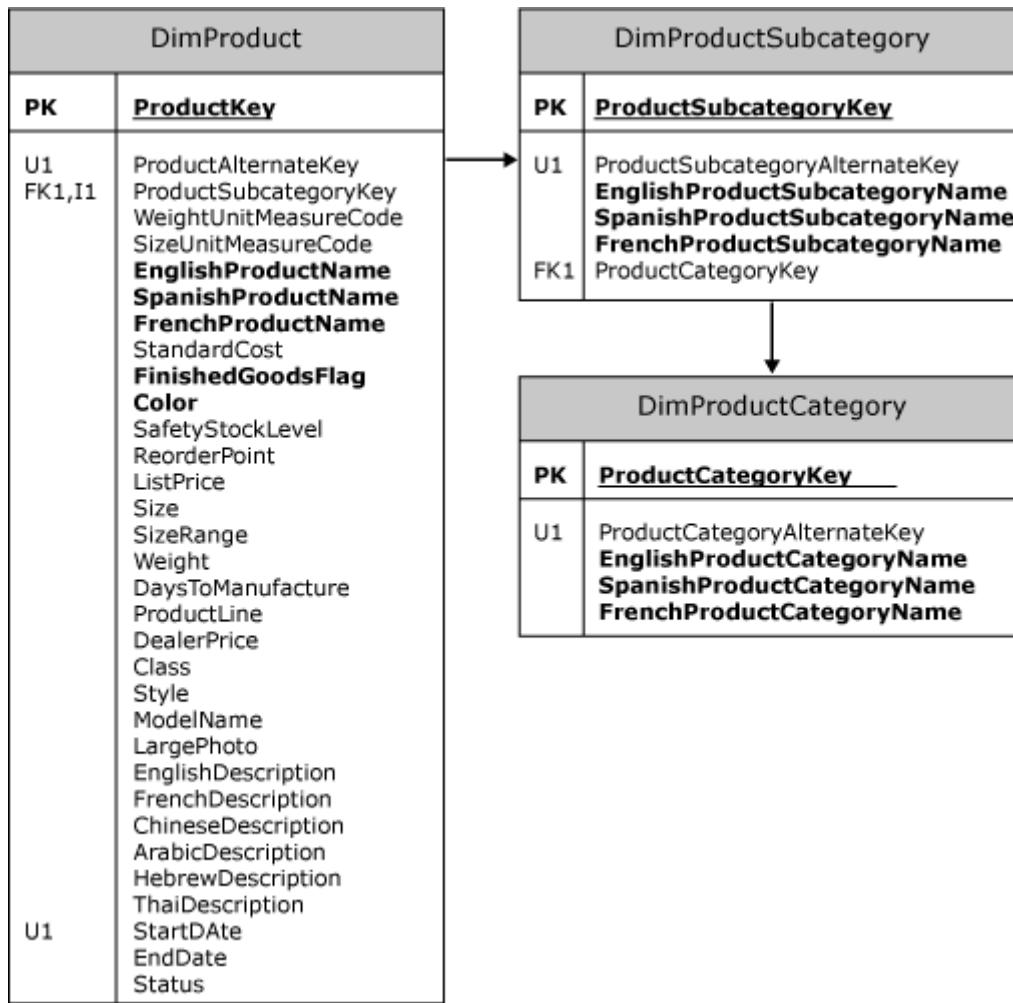

The structure of a dimension is largely driven by the structure of the underlying dimension table or tables. The simplest structure is called a star schema, where each dimension is based on a single dimension table that is directly linked to the fact table by a primary key - foreign key relationship.

The following diagram illustrates a subsection of the **AdventureWorksDW2012** sample database, in which the **FactResellerSales** fact table is related to two dimension tables, **DimReseller** and **DimPromotion**. The **ResellerKey** column in the **FactResellerSales** fact table defines a foreign key relationship to the **ResellerKey** primary key column in the **DimReseller** dimension table. Similarly, the **PromotionKey** column in the **FactResellerSales** fact table defines a foreign key relationship to the **PromotionKey** primary key column in the **DimPromotion** dimension table.

Dimension based on a Snowflake Schema Design

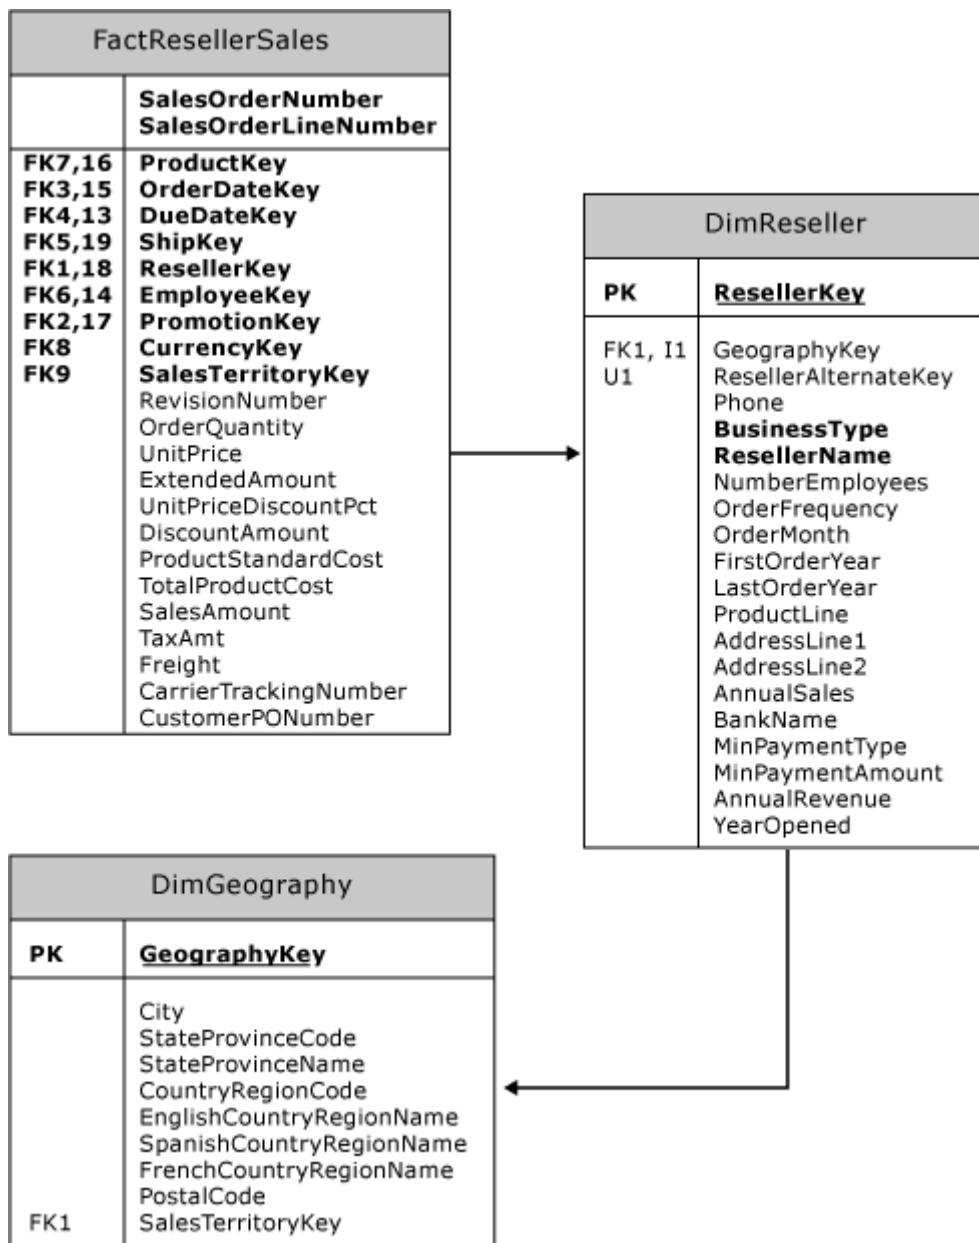

Frequently, a more complex structure is required because information from multiple tables is required to define the dimension. In this structure, called a snowflake schema, each dimension is based on attributes from columns in multiple tables linked to each other and ultimately to the fact table by primary key - foreign key relationships. For example, the following diagram illustrates the tables required to completely describe the Product dimension in the AdventureWorksDW sample project:

To completely describe a product, the product's category and subcategory must be included in the Product dimension. However, that information does not reside directly in the main table for the **DimProduct** dimension. A foreign key relationship from **DimProduct** to **DimProductSubcategory**, which in turn has a foreign key relationship to the **DimProductCategory** table, makes it possible to include the information for product categories and subcategories in the Product dimension.

Snowflake Schema versus Reference Relationship

Sometimes, you may have a choice between using a snowflake schema to define attributes in a dimension from multiple tables, or defining two separate dimensions and defining a reference dimension relationship between them. The following diagram illustrates such a scenario.

In the previous diagram, the **FactResellerSales** fact table does not have a foreign key relationship with the **DimGeography** dimension table. However, the **FactResellerSales** fact table does have a foreign key relationship with the **DimReseller** dimension table, which in turn has a foreign key relationship with the **DimGeography** dimension table. To define a Reseller dimension that contains geography information about each reseller, you would have to retrieve these attributes from the **DimGeography** and the **DimReseller** dimension tables. However, in SQL Server Analysis Services, you can achieve the same result by creating two separate dimensions and linking them in a measure group by defining a reference dimension relationship between the two dimensions. For more information about reference dimension relationships, see [Dimension Relationships](#).

One advantage of using reference dimension relationships in this scenario is that you could create a single geography dimension and then create multiple cube dimensions based on the geography dimension, without requiring any additional storage space. For example, you could link one of the geography cube dimensions to a reseller dimension

and another of the geography cube dimensions to a customer dimension. [Related topics](#): Dimension Relationships, Define a Referenced Relationship and Referenced Relationship Properties

Processing a Dimension

After you create a dimension, you must process the dimension before you can view the members of the attributes and hierarchies in the dimension. After the structure of a dimension is changed or the information in its underlying tables is updated, you have to process the dimension again before you can view the changes. When you process a dimension after structural changes, you must also process any cubes that include the dimension - or the cube will not be viewable.

Security

All the subordinate objects of a dimension, including hierarchies, levels, and members, are secured using roles in SQL Server Analysis Services. Dimension security can be applied for all the cubes in the database that use the dimension, or for only a specific cube. For more information about dimension security, see [Grant permissions on a dimension \(Analysis Services\)](#).

Dimensions - Storage

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Dimensions in Microsoft SQL Server SQL Server Analysis Services support two storage modes:

- Relational OLAP (ROLAP)
- Multidimensional OLAP (MOLAP)

The storage mode determines the location and form of a dimension's data. MOLAP is the default storage mode for dimensions. Related topics:[Partition Storage Modes and Processing](#)

MOLAP

Data for a dimension that uses MOLAP is stored in a multidimensional structure in the instance of SQL Server Analysis Services. This multidimensional structure is created and populated when the dimension is processed. MOLAP dimensions provide better query performance than ROLAP dimensions.

ROLAP

Data for a dimension that uses ROLAP is actually stored in the tables used to define the dimension. The ROLAP storage mode can be used to support large dimensions without duplicating large amounts of data, but at the expense of query performance. Because the dimension relies directly on the tables in the data source view used to define the dimension, the ROLAP storage mode also supports real-time OLAP.

Important

If a dimension uses the ROLAP storage mode and the dimension is included in a cube that uses MOLAP storage, any schema changes to its source table must be followed by immediate processing of the cube. Failure to do this may result in inconsistent results when querying the cube. Related topic:[Automate Analysis Services Administrative Tasks with SSIS](#).

Proactive Caching (Dimensions)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Proactive caching provides automatic MOLAP cache creation and management for OLAP objects. The cubes immediately incorporate changes that are made to the data in the database, based upon notifications received from the database. The goal of proactive caching is to provide the performance of traditional MOLAP, while retaining the immediacy and ease of management offered by ROLAP.

A simple [ProactiveCaching](#) object is composed of: timing specification, and table notification. The timing specification defines the timeframe for updating the cache after a change notification has been received. The table notification defines the notification schema between the data table and the [ProactiveCaching](#) object.

User Hierarchies - Level Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The following table lists and describes the properties of a level in a user-defined hierarchy.

 Expand table

Property	Description
Description	Contains the description of the level.
HideMemberIf	Indicates whether and when a member in a level should be hidden from client applications. This property can have the following values: Never Members are never hidden. This is the default value. OnlyChildWithNoName A member is hidden when the member is the only child of its parent and the member's name is empty. OnlyChildWithParentName A member is hidden when the member is the only child of its parent and the member's name is identical to that of its parent. NoName A member is hidden when the member's name is empty. ParentName A member is hidden when the member's name is identical to that of its parent.
ID	Contains the unique identifier (ID) of the level.
Name	Contains the friendly name of the level. By default, the name of a level is the same as the name of the source attribute.
SourceAttribute	Contains the name of the source attribute on which the level is based.

User Hierarchies

Article • 12/09/2022

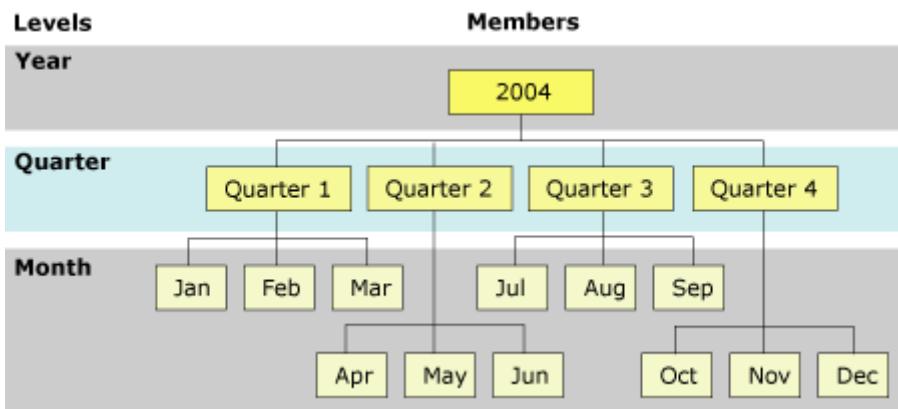

Applies to: ✓ SQL Server Analysis Services ✖ Azure Analysis Services ✖
Fabric/Power BI Premium

User-defined hierarchies are user-defined hierarchies of attributes that are used in Microsoft SQL Server SQL Server Analysis Services to organize the members of a dimension into hierarchical structures and provide navigation paths in a cube. For example, the following table defines a dimension table for a time dimension. The dimension table supports three attributes, named Year, Quarter, and Month.

[] Expand table

Year	Quarter	Month
1999	Quarter 1	Jan
1999	Quarter 1	Feb
1999	Quarter 1	Mar
1999	Quarter 2	Apr
1999	Quarter 2	May
1999	Quarter 2	Jun
1999	Quarter 3	Jul
1999	Quarter 3	Aug
1999	Quarter 3	Sep
1999	Quarter 4	Oct
1999	Quarter 4	Nov
1999	Quarter 4	Dec

The Year, Quarter, and Month attributes are used to construct a user-defined hierarchy, named Calendar, in the time dimension. The relationship between the levels and members of the Calendar dimension (a regular dimension) is shown in the following diagram.

! Note

Any hierarchy other than the default two-level attribute hierarchy is called a user-defined hierarchy. For more information about attribute hierarchies, see [Attributes and Attribute Hierarchies](#).

Member Structures

With the exception of parent-child hierarchies, the positions of members within the hierarchy are controlled by the order of the attributes in the hierarchy's definition. Each attribute in the hierarchy definition constitutes a level in the hierarchy. The position of a member within a level is determined by the ordering of the attribute used to create the level. The member structures of user-defined hierarchies can take one of four basic forms, depending on how the members are related to each other.

Balanced Hierarchies

In a balanced hierarchy, all branches of the hierarchy descend to the same level, and each member's logical parent is the level immediately above the member. The Product Categories hierarchy of the Product dimension in the Adventure Works DW Multidimensional 2012 sample SQL Server Analysis Services database is a good example of a balanced hierarchy. Each member in the Product Name level has a parent member in the Subcategory level, which in turn has a parent member in the Category level. Also, every branch in the hierarchy has a leaf member in the Product Name level.

Unbalanced Hierarchies

In an unbalanced hierarchy, branches of the hierarchy descend to different levels. Parent-child hierarchies are unbalanced hierarchies. For example, the Organization dimension in the Adventure Works DW Multidimensional 2012 sample SQL Server

Analysis Services database contains a member for each employee. The CEO is the top member in the hierarchy, and the division managers and executive secretary are immediately beneath the CEO. The division managers have subordinate members but the executive secretary does not.

It may be impossible for end users to distinguish between unbalanced and ragged hierarchies. However, you employ different techniques and properties in SQL Server Analysis Services to support these two types of hierarchies. For more information, see [Ragged Hierarchies](#), and [Attributes in Parent-Child Hierarchies](#).

Ragged Hierarchies

In a ragged hierarchy, the logical parent member of at least one member is not in the level immediately above the member. This can cause branches of the hierarchy to descend to different levels. For example, in a Geography dimension defined with the levels Continent, CountryRegion, and City, in that order, the member Europe appears in the top level of the hierarchy, the member France appears in the middle level, and the member Paris appears in the bottom level. France is more specific than Europe, and Paris is more specific than France. To this regular hierarchy, the following changes are made:

- The Vatican City member is added to the CountryRegion level.
- Members are added to the City level and are associated with the Vatican City member in the CountryRegion level.
- A level, named Province, is added between the CountryRegion and City levels.

The Province level is populated with members associated with other members in the CountryRegion level, and members in the City level are associated with their corresponding members in the Province level. However, because the Vatican City member in the CountryRegion level has no associated members in the Province level, members must be associated from the City level directly to the Vatican City member in the CountryRegion level. Because of the changes, the hierarchy of the dimension is now ragged. The parent of the city Vatican City is the country/region Vatican City, which is not in the level immediately above the Vatican City member in the City level. For more information, see [Ragged Hierarchies](#).

Parent-Child Hierarchies

Parent-child hierarchies for dimensions are defined by using a special attribute, called a parent attribute, to determine how members relate to each other. A parent attribute describes a *self-referencing relationship*, or *self-join*, within a dimension main table.

Parent-child hierarchies are constructed from a single parent attribute. Only one level is assigned to a parent-child hierarchy, because the levels present in the hierarchy are drawn from the parent-child relationships between members associated with the parent attribute. The dimension schema of a parent-child hierarchy depends on a self-referencing relationship present on the dimension main table. For example, the following diagram illustrates the **DimOrganization** dimension main table in the Adventure Works DW Multidimensional 2012SQL Server Analysis Services sample database.

DimOrganization	
PK	OrganizationKey
FK2	ParentOrganizationKey PercentageOfOwnership OrganizationName ParentOrganizationName CurrencyKey
FK1	

In this dimension table, the **ParentOrganizationKey** column has a foreign key relationship with the **OrganizationKey** primary key column. In other words, each record in this table can be related through a parent-child relationship with another record in the table. This kind of self-join is generally used to represent organization entity data, such as the management structure of employees in a department.

When you create a parent-child hierarchy, the columns represented by both attributes must have the same data type. Both attributes must also be in the same table. By default, any member whose parent key equals its own member key, null, 0 (zero), or a value absent from the column for member keys is assumed to be a member of the top level (excluding the (All) level).

The depth of a parent-child hierarchy can vary among its hierarchical branches. In other words, a parent-child hierarchy is considered an unbalanced hierarchy.

Unlike user-defined hierarchies, in which the number of levels in the hierarchy determines the number of levels that can be seen by end users, a parent-child hierarchy is defined with the single level of an attribute hierarchy, and the values in this single level produce the multiple levels seen by users. The number of displayed levels depends on the contents of the dimension table columns that store the member keys and the parent keys. The number of levels can change when the data in the dimension tables change. For more information, see [Parent-Child Dimensions](#), and [Attributes in Parent-Child Hierarchies](#).

Write-Enabled Dimensions

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Important

This feature will be removed in the next version of Microsoft SQL Server. Avoid using this feature in new development work, and plan to modify applications that currently use this feature.

The data in a dimension is generally read-only. However, for certain scenarios, you may want to write-enable a dimension. In Microsoft SQL Server SQL Server Analysis Services, write-enabling a dimension enables business users to modify the contents of the dimension and see the immediate effect of changes on the hierarchies of the dimension. Any dimension that is based on a single table can be write-enabled. In a write-enabled dimension, business users and administrators can change, move, add, and delete attribute members within the dimension. These updates are referred to collectively as *dimension writeback*.

SQL Server Analysis Services supports dimension writeback on all dimension attributes and any member of a dimension may be modified. For a write-enabled cube or partition, updates are stored in a writeback table separate from the cube's source tables. However, for a write-enabled dimension, updates are recorded directly in the dimension's table. Also, if the write-enabled dimension is included in a cube with multiple partitions where some or all their data sources have copies of the dimension table, only the original dimension table is updated during a writeback process.

Write-enabled dimensions and write-enabled cubes have different but complementary features. A write-enabled dimension gives business users the ability to update members, whereas a write-enabled cube gives them the ability to update cell values. Although these two features are complementary, you do not have to use both features in combination. A dimension does not have to be included in a cube for dimension writeback to occur. A write-enabled dimension can also be included in a cube that is not write-enabled. You use different procedures to write-enable dimensions and cubes, and to maintain their security.

The following restrictions apply to dimension writeback:

- When you create a new member, you must include every attribute in a dimension. You cannot insert a member without specifying a value for the key attribute of the dimension. Therefore, creating members is subject to any constraints (such as non-null key values) that are defined on the dimension table.
- Dimension writeback is supported only for star schemas. In other words, a dimension must be based on a single dimension table directly related to a fact table. After you write-enable a dimension, SQL Server Analysis Services validates this requirement when you deploy to an existing SQL Server Analysis Services database or when you build an SQL Server Analysis Services project.

Any existing member of a writeback dimension can be modified or deleted. When a member is deleted, the deletion cascades to all child members. For example, in a Customer dimension that contains CountryRegion, Province, City, and Customer attributes, deleting a country/region would delete all provinces, cities, and customers that belong to the deleted country/region. If a country/region has only one province, deleting that province would delete the country/region also.

Members of a writeback dimension can only be moved within the same level. For example, a city could be moved to the City level in a different country/region or province, but a city cannot be moved to the Province or CountryRegion level. In a parent-child hierarchy, all members are leaf members, and therefore a member may be moved to any level other than the **(All)** level.

If a member of a parent-child hierarchy is deleted, the member's children are moved to the member's parent. Update permissions on the relational table are required on the deleted member, but no permissions are required on the moved members. When an application moves a member in a parent-child hierarchy, the application can specify in the UPDATE operation whether descendants of the member are moved with the member or are moved to the member's parent. To recursively delete a member in a parent-child hierarchy, a user must have update permissions on the relational table for the member and all the member's descendants.

 **Note**

Updates to the parent attribute in a parent-child hierarchy must not include updates to any other properties or attributes.

All changes to a dimension cause the dimension structure to be modified. Each change to a dimension is considered a single transaction, requiring incremental processing to update the dimension structure. Write-enabled dimensions have the same processing requirements as any other dimension.

Note

Dimension writeback is not supported by linked dimensions.

Security

The only business users who can update a write-enabled dimension are those in SQL Server Analysis Services database roles that have been granted read/write permission to the dimension. For each role, you can control which members can and cannot be updated. For business users to update write-enabled dimensions, their client application must support this capability. For such users, a write-enabled dimension must be included in a cube that was processed since the dimension last changed. For more information, see [Authorizing access to objects and operations \(Analysis Services\)](#).

Users and groups included in the Administrators role can update the attribute members of a write-enabled dimension, even if the dimension is not included in a cube.

Aggregations and Aggregation Designs

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

An [AggregationDesign](#) object defines a set of aggregation definitions that can be shared across multiple partitions.

An [Aggregation](#) object represents the summarization of measure group data at certain granularity of the dimensions.

A simple [Aggregation](#) object is composed of: basic information and dimensions. Basic information includes the name of the aggregation, the ID, annotations, and a description. The dimensions are a collection of [AggregationDimension](#) objects that contain the list of granularity attributes for the dimension.

Aggregations are precalculated summaries of data from leaf cells. Aggregations improve query response time by preparing the answers before the questions are asked. For example, when a data warehouse fact table contains hundreds of thousands of rows, a query requesting the weekly sales totals for a particular product line can take a long time to answer if all the rows in the fact table have to be scanned and summed at query time to compute the answer. However, the response can be almost immediate if the summarization data to answer this query has been precalculated. This precalculation of summary data occurs during processing and is the foundation for the rapid response times of OLAP technology.

Cubes are the way that OLAP technology organizes summary data into multidimensional structures. Dimensions and their hierarchies of attributes reflect the queries that can be asked of the cube. Aggregations are stored in the multidimensional structure in cells at coordinates specified by the dimensions. For example, the question "What were the sales of product X in 1998 for the Northwest region?" involves three dimensions (Product, Time, and Geography) and one measure (Sales). The value of the cell in the cube at the specified coordinates (product X, 1998, Northwest) is the answer, a single numeric value.

Other questions may return multiple values. For example, "How much were the sales of hardware products by quarter by region for 1998?" Such queries return sets of cells from the coordinates that satisfy the specified conditions. The number of cells returned by the query depends on the number of items in the Hardware level of the Product dimension, the four quarters in 1998, and the number of regions in the Geography dimension. If all summary data has been precalculated into aggregations, the response time of the query

will depend only on the time that is required to extract the specified cells. No calculation or reading of data from the fact table is required.

Although precalculation of all possible aggregations in a cube might provide the fastest possible response time for all queries, SQL Server Analysis Services can easily calculate some aggregated values from other precalculated aggregations. Additionally, calculating all possible aggregations requires significant processing time and storage. Therefore, there is a tradeoff between storage requirements and the percentage of possible aggregations that are precalculated. If no aggregations are precalculated (0%), the amount of required processing time and storage space for a cube is minimized, but query response time may be slow because the data required to answer each query must be retrieved from the leaf cells and then aggregated at query time to answer each query. For example, returning a single number that answers the question asked earlier ("What were the sales of product X in 1998 for the Northwest region") might require reading thousands of rows of data, extracting the value of the column used to provide the Sales measure from each row, and then calculating the sum. Moreover, the length of time required to retrieve that data will vary depending on the storage mode chosen for the data-MOLAP, HOLAP, or ROLAP.

Designing Aggregations

Microsoft SQL Server SQL Server Analysis Services incorporates a sophisticated algorithm to select aggregations for precalculation so that other aggregations can be quickly computed from the precalculated values. For example, if the aggregations are precalculated for the Month level of a Time hierarchy, the calculation for a Quarter level requires only the summarization of three numbers, which can be quickly computed on demand. This technique saves processing time and reduces storage requirements, with minimal effect on query response time.

The Aggregation Design Wizard provides options for you to specify storage and percentage constraints on the algorithm to achieve a satisfactory tradeoff between query response time and storage requirements. However, the Aggregation Design Wizard's algorithm assumes that all possible queries are equally likely. The Usage-Based Optimization Wizard lets you adjust the aggregation design for a measure group by analyzing the queries that have been submitted by client applications. By using the wizard to tune a cube's aggregation you can increase responsiveness to frequent queries and decrease responsiveness to infrequent queries without significantly affecting the storage needed for the cube.

Aggregations are designed by using the wizards but are not actually calculated until the partition for which the aggregations are designed is processed. After the aggregation

has been created, if the structure of a cube ever changes, or if data is added to or changed in a cube's source tables, it is usually necessary to review the cube's aggregations and process the cube again.

Calculations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A calculation is a Multidimensional Expressions (MDX) expression or script that is used to define a calculated member, a named set, or a scoped assignment in a cube in Microsoft SQL Server SQL Server Analysis Services. Calculations let you add objects that are defined not by the data of the cube, but by expressions that can reference other parts of the cube, other cubes, or even information outside the SQL Server Analysis Services database. Calculations let you extend the capabilities of a cube, adding flexibility and power to business intelligence applications. For more information about scripting calculations, see [Introduction to MDX Scripting in Microsoft SQL Server 2005](#).

Calculated Members

A calculated member is a member whose value is calculated at run time using a Multidimensional Expressions (MDX) expression that you specify when you define the calculated member. A calculated member is available to business intelligence applications just like any other member. Calculated members do not increase the size of the cube because only the definitions are stored in the cube; values are calculated in memory as required to answer a query.

Calculated members can be defined for any dimension, including the measures dimension. Calculated members created on the Measures dimension are called calculated measures.

Although calculated members are typically based on data that already exists in the cube, you can create complex expressions by combining data with arithmetic operators, numbers, and functions. You can also use MDX functions, such as `LookupCube`, to access data in other cubes in the SQL Server Analysis Services database. SQL Server Analysis Services includes standardized Visual Studio function libraries, and you can use stored procedures to retrieve data from sources other than the current SQL Server Analysis Services database. For more information about stored procedures, see [Defining Stored Procedures](#).

For example, suppose executives in a shipping company want to determine which types of cargo are more profitable to carry, based on profit per unit of volume. They use a Shipments cube that contains the dimensions Cargo, Fleet, and Time and the measures `Price_to_Ship`, `Cost_to_Ship`, and `Volume_in_Cubic_Meters`; however, the cube does not

contain a measure for profitability. You can create a calculated member as a measure named Profit_per_Cubic_Meter in the cube by combining the existing measures in the following expression:

```
([Measures].[Price_to_Ship] - [Measures].[Cost_to_Ship]) /  
[Measures].[Volume_in_Cubic_Meters]
```

After you create the calculated member, the Profit_per_Cubic_Meter appears together with the other measures the next time that the Shipments cube is browsed.

To create calculated members, use the **Calculations** tab in Cube Designer. For more information, see [Create Calculated Members](#)

Named Sets

A named set is a CREATE SET MDX statement expression that returns a set. The MDX expression is saved as part of the definition of a cube in Microsoft SQL Server SQL Server Analysis Services. A named set is created for reuse in Multidimensional Expressions (MDX) queries. A named set enables business users to simplify queries, and use a set name instead of a set expression for complex, frequently used set expressions.

Related topic: [Create Named Sets](#)

Script Commands

A script command is an MDX script, included as part of the definition of the cube. Script commands let you perform almost any action that is supported by MDX on a cube, such as scoping a calculation to apply to only part of the cube. In SQL Server SQL Server Analysis Services, MDX scripts can apply either to the whole cube or to specific sections of the cube, at specific points throughout the execution of the script. The default script command, which is the CALCULATE statement, populates cells in the cube with aggregated data based on the default scope.

The default scope is the whole cube, but you can define a more limited scope, known as a subcube, and then apply an MDX script to only that particular cube space. The SCOPE statement defines the scope of all subsequent MDX expressions and statements in the calculation script until the scope is terminated or redefined. The THIS statement is then used to apply an MDX expression to the current scope. You can use the BACK_COLOR statement to specify a background cell color for the cells in the current scope, to help you during debugging.

For example, you can use a script command to allocate sales quotas to employees across time and sales territory based on the weighted values of sales for a prior time period.

Cube Cells (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

A cube is composed of cells, organized by measure groups and dimensions. A cell represents the unique logical intersection in a cube of one member from every dimension in the cube. For example, the cube described by the following diagram contains one measure group that has two measures, organized along three dimensions named Source, Route, and Time.

The single shaded cell in this diagram is the intersection of the following members:

- The air member of the Route dimension.
- The Africa member of the Source dimension.
- The 4th quarter member of the Time dimension.
- The Packages measure.

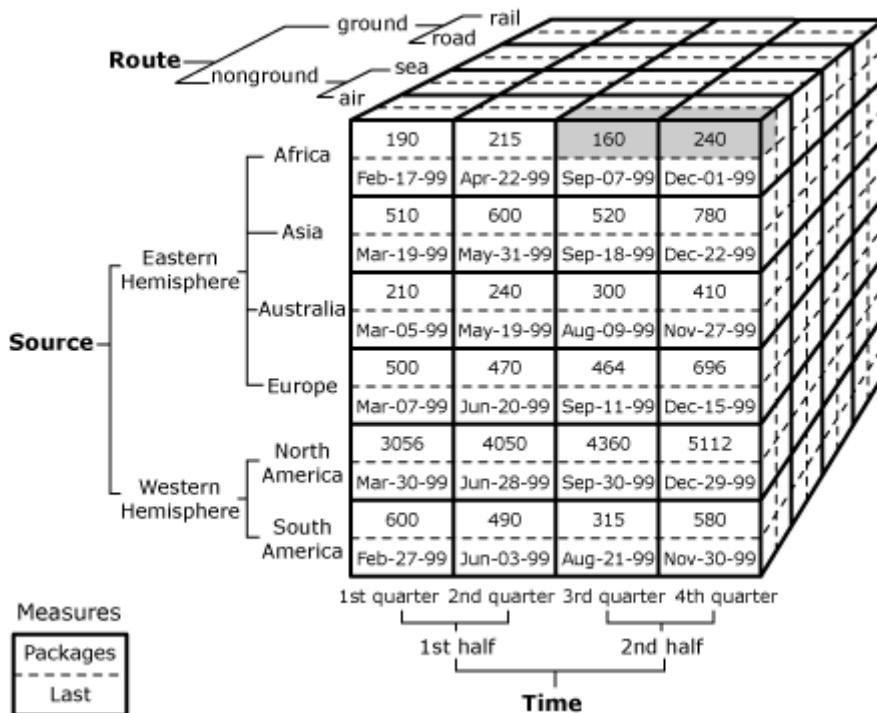

Leaf and Nonleaf Cells

The value for a cell in a cube can be obtained in one of several ways. In the previous example, the value in the cell can be directly retrieved from the fact table of the cube, because all the members used to identify that cell are *leaf members*. A leaf member has no child members, hierarchically speaking, and typically references a single record in a dimension table. This kind of cell is referred to as a *leaf cell*.

However, a cell can also be identified by using *nonleaf members*. A nonleaf member is a member that has one or more child members. In this case, the value of the cell is typically derived from the aggregation of child members associated with the nonleaf member. For example, the intersection of the following members and dimensions refers to a cell whose value is supplied by aggregation:

- The air member of the Route dimension.
 - The Africa member of the Source dimension.
 - The 2nd half member of the Time dimension.
 - The Packages member.

The 2nd half member of the Time dimension is a nonleaf member. Therefore, all of values associated with it must be aggregated values, as shown in the following diagram.

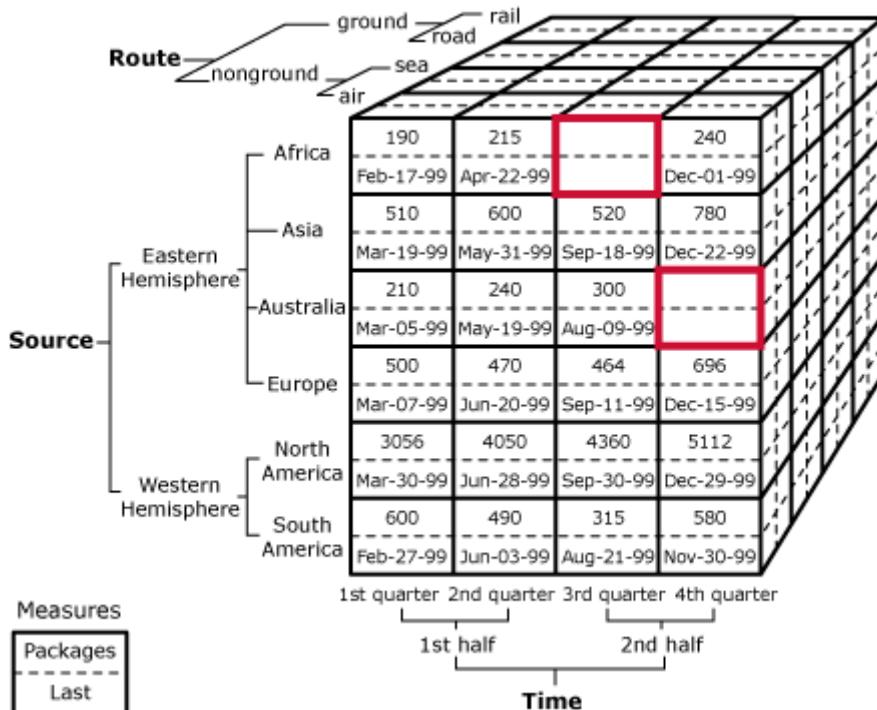

Assuming the aggregations for the 3rd quarter and 4th quarter members are summations, the value of the specified cell is 400, which is the total of all of the leaf cells shaded in the previous diagram. Because the value of the cell is derived from the aggregation of other cells, the specified cell is considered a *nonleaf cell*.

The cell values derived for members that use custom rollups and member groups, in addition to custom members, are handled similarly. However, cell values derived for calculated members are based completely on the Multidimensional Expressions (MDX) expression used to define the calculated member; in some cases, there may be no actual cell data involved. For more information, see [Custom Rollup Operators in Parent-Child Dimensions](#), [Define Custom Member Formulas](#), and [Calculations](#).

Empty Cells

It is not required that every cell in a cube contain a value; there can be intersections in a cube that have no data. These intersections, called empty cells, frequently occur in cubes because not every intersection of a dimension attribute with a measure within a cube contains a corresponding record in a fact table. The ratio of empty cells in a cube to the total number of cells in a cube is frequently referred to as the *sparsity* of a cube.

For example, the structure of the cube shown in the following diagram is similar to other examples in this topic. However, in this example, there were no air shipments to Africa for the third quarter or to Australia for the fourth quarter. There is no data in the fact table to support the intersections of those dimensions and measures; therefore the cells at those intersections are empty.

In SQL Server SQL Server Analysis Services, an empty cell is a cell that has special qualities. Because empty cells can skew the results of crossjoins, counts, and so on, many MDX functions supply the ability to ignore empty cells for the purposes of calculation. For more information, see [Multidimensional Expressions \(MDX\) Reference](#), and [Key Concepts in MDX \(Analysis Services\)](#).

Security

Access to cell data is managed in SQL Server Analysis Services at the role level, and can be finely controlled by using MDX expressions. For more information, see [Grant custom access to dimension data \(Analysis Services\)](#), and [Grant custom access to cell data \(Analysis Services\)](#).

Cube Objects (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Introducing Cube Objects

A simple [Cube](#) object is composed of: basic information, dimensions, and measure groups. Basic information includes the name of the cube, the default measure of the cube, the data source, the storage mode, and others.

The Dimensions collection contains the actual set of dimensions used in the cube from the database dimensions collection. All dimensions have to be defined in the dimensions collection of the database before being referenced in the cube. Private dimensions are not available in Microsoft SQL Server SQL Server Analysis Services.

Measure groups are sets of measures in the cube. A measure group is a collection of measures that have a common data source view and a common set of dimensions. A measure group is the unit of process for measures; measure groups can be processed individually and then browsed.

Cube Properties - Multidimensional Model Programming

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Cubes have a number of properties that you can set to affect cube-wide behavior. These properties are summarized in the following table.

Note

Some properties are set automatically when the cube is created and cannot be changed.

For more information about how to set cube properties, see [Cube Designer \(Analysis Services - Multidimensional Data\)](#).

 Expand table

Property	Description
AggregationPrefix	Specifies the common prefix that is used for aggregation names.
Collation	Specifies the locale identifier (LCID) and the comparison flag, separated by an underscore: for example, Latin1_General_C1_AS.
DefaultMeasure	Contains a Multidimensional Expressions (MDX) expression that defines the default measure for the cube.
Description	Provides a description of the cube, which may be exposed in client applications.
ErrorConfiguration	Contains configurable error handling settings for handling of duplicate keys, unknown keys, error limits, action upon error detection, error log file, and null key handling.
EstimatedRows	Specifies the number of estimated rows in the cube.
ID	Contains the unique identifier (ID) of the cube.
Language	Specifies the default language identifier of the cube.
Name	Specifies the user-friendly name of the cube.

Property	Description
ProactiveCaching	Defines proactive cache settings for the cube.
ProcessingMode	Indicates whether indexing and aggregating should occur during or after processing. Options are regular or lazy .
ProcessingPriority	Determines the processing priority of the cube during background operations, such as lazy aggregations and indexing. The default value is 0.
ScriptCacheProcessingMode	Indicates whether the script cache should be built during or after processing. Options are regular and lazy .
ScriptErrorHandlingMode	Determines error handling. Options are IgnoreNone or IgnoreAll .
Source	Displays the data source view used for the cube.
StorageLocation	Specifies the file system storage location for the cube. If none is specified, the location is inherited from the database that contains the cube object.
StorageMode	Specifies the storage mode for the cube. Values are MOLAP , ROLAP , or HOLAP .
Visible	Determines the visibility of the cube.

 **Note**

For more information about setting values for the ErrorConfiguration property when working with null values and other data integrity issues, see [Handling Data Integrity Issues in Analysis Services 2005](#).

Cube Storage (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Storage may include only the cube metadata, or may include all of the source data from the fact table as well as the aggregations defined by dimensions related to the measure group. The amount of data stored depends upon the storage mode selected and the number of aggregations. The amount of data stored directly affects query performance. Microsoft SQL Server SQL Server Analysis Services uses several techniques for minimizing the space required for storage of cube data and aggregations:

- Storage options enable you to select the storage modes and locations that are most appropriate for cube data.
- A sophisticated algorithm designs efficient summary aggregations to minimize storage without sacrificing speed.
- Storage is not allocated for empty cells.

Storage is defined on a partition-by-partition basis, and at least one partition exists for each measure group in a cube. For more information, see [Partitions \(Analysis Services - Multidimensional Data\)](#), [Partition Storage Modes and Processing, Measures and Measure Groups](#), and [Create Measures and Measure Groups in Multidimensional Models](#).

Partition Storage

Storage for a measure group can be divided into multiple partitions. Partitions enable you to distribute a measure group into discrete segments on a single server or across multiple servers, and to optimize storage and query performance. Each partition in a measure group can be based on a different data source and stored using different storage settings.

You specify the data source for a partition when you create it. You can also change the data source for any existing partition. A measure group can be partitioned vertically or horizontally. Each partition in a vertically partitioned measure group is based on a filtered view of a single source table. For example, if a measure group is based on a single table that contains several years of data, you could create a separate partition for

each year's data. In contrast, each partition in a horizontally partitioned measure group is based on a separate table. You would use horizontal partitions if the data source stores each year's data in a separate table.

Partitions are initially created with the same storage settings as the measure group in which they are created. The storage settings determine whether the detail and aggregation data is stored in multidimensional format on the instance of SQL Server Analysis Services, in relational format on the source server, or a combination of both. Storage settings also determine whether proactive caching is used to automatically process source data changes to the multidimensional data stored on the SQL Server Analysis Services.

The partitions of a cube are not visible to the user. However, the choice of storage settings for different partitions may affect the immediacy of data, the amount of disk space that is used, and query performance. Partitions can be stored on multiple instances of SQL Server Analysis Services. This provides a clustered approach to cube storage, and distributes workload across SQL Server Analysis Services servers. For more information, see [Partition Storage Modes and Processing](#), [Remote Partitions](#), and [Partitions \(Analysis Services - Multidimensional Data\)](#).

Linked Measure Groups

It can require considerable disk space to store multiple copies of a cube on different instances of SQL Server Analysis Services, but you can greatly reduce the space needed by replacing the copies of the measure group with linked measure groups. A linked measure group is based on a measure group in a cube in another SQL Server Analysis Services database, on the same or a different instance of SQL Server Analysis Services. A linked measure group can also be used with linked dimensions from the same source cube. The linked dimensions and measure groups use the aggregations of the source cube and have no data storage requirements of their own. Therefore, by maintaining the source measure groups and dimensions in one database, and creating linked cubes and dimensions in cubes in other databases, you can save disk space that otherwise would be used for storage. For more information, see [Linked Measure Groups](#).

Cube Translations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A translation is a simple mechanism to change the displayed labels and captions from one language to another. Each translation is defined as a pair of values: a string with the translated text, and a number with the language ID. Translations are available for all objects in SQL Server Analysis Services. Dimensions can also have the attribute values translated. The client application is responsible for finding the language setting that the user has defined, and switch to display all captions and labels to that language. An object can have as many translations as you want.

A simple [Translation](#) object is composed of: language ID number, and translated caption. The language ID number is an [Integer](#) with the language ID. The translated caption is the translated text.

In Microsoft SQL Server SQL Server Analysis Services, a cube translation is a language-specific representation of the name of a cube object, such as a caption or a display folder. SQL Server Analysis Services also supports translations of dimension and member names.

Translations provide server support for client applications that can support multiple languages. Frequently, users from different countries/regions view cube data. It is useful to be able to translate various elements of a cube into a different language so that these users can view and understand the cube's metadata. For example, a business user in France can access a cube from a workstation with a French locale setting, and view the object property values in French. Similarly, a business user in Germany can access the same cube from a workstation with a German locale setting and view the object property values in German.

The collation and language information for the client computer is stored in the form of a locale identifier (LCID). Upon connection, the client passes the LCID to the instance of SQL Server Analysis Services. The instance uses the LCID to determine which set of translations to use when providing metadata for SQL Server Analysis Services objects to each business user. If an SQL Server Analysis Services object does not contain the specified translation, the default language is used to return the content back to the client.

Dimension Relationships

Article • 12/09/2022

Applies to: ✓ SQL Server Analysis Services ✖ Azure Analysis Services ✖
Fabric/Power BI Premium

Dimension usage defines the relationships between a cube dimension and the measure groups in a cube. A cube dimension is an instance of a database dimension that is used in a specific cube. A cube can, and frequently does, have cube dimensions that are not directly related to a measure group, but which might be indirectly related to the measure group through another dimension or measure group. When you add a database dimension or measure group to a cube, Microsoft SQL Server SQL Server Analysis Services tries to determine dimension usage by examining relationships between the dimension tables and fact tables in the cube's data source view, and by examining the relationships between attributes in dimensions. SQL Server Analysis Services automatically sets the dimension usage settings for the relationships that it can detect.

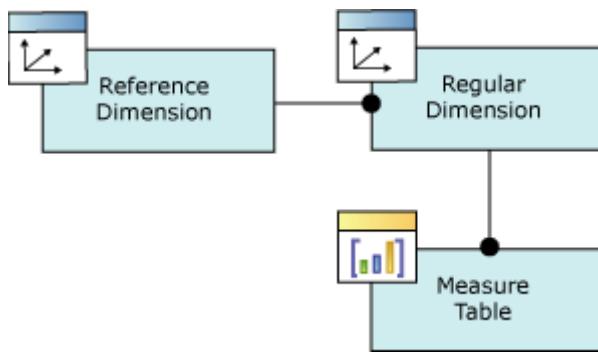

A relationship between a dimension and a measure group consists of the dimension and fact tables participating in the relationship and a granularity attribute that specifies the granularity of the dimension in the particular measure group.

Regular Dimension Relationships

A regular dimension relationship between a cube dimension and a measure group exists when the key column for the dimension is joined directly to the fact table. This direct relationship is based on a primary key-foreign key relationship in the underlying relational database, but might also be based on a logical relationship that is defined in the data source view. A regular dimension relationship represents the relationship between dimension tables and a fact table in a traditional star schema design. For more information about regular relationships, see [Define a Regular Relationship and Regular Relationship Properties](#).

Reference Dimension Relationships

A reference dimension relationship between a cube dimension and a measure group exists when the key column for the dimension is joined indirectly to the fact table through a key in another dimension table, as shown in the following illustration.

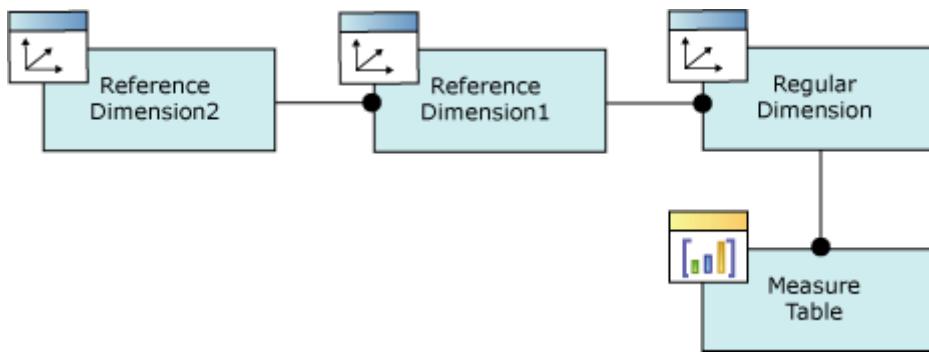

A reference dimension relationship represents the relationship between dimension tables and a fact table in a snowflake schema design. When dimension tables are connected in a snowflake schema, you can define a single dimension using columns from multiple tables, or you can define separate dimensions based on the separate dimension tables and then define a link between them using the reference dimension relationship setting. The following figure shows one fact table named **InternetSales**, and two dimension tables called **Customer** and **Geography**, in a snowflake schema.

You can create a dimension with the **Customer** table as the dimension main table and the **Geography** table included as a related table. A regular relationship is then defined between the dimension and the InternetSales measure group.

Alternatively, you can create two dimensions related to the InternetSales measure group: a dimension based on the **Customer** table, and a dimension based on the **Geography** table. You can then relate the Geography dimension to the InternetSales measure group using a reference dimension relationship using the Customer dimension. In this case, when the facts in the InternetSales measure group are dimensioned by the Geography dimension, the facts are dimensioned by customer and by geography. If the cube contained a second measure group named Reseller Sales, you would be unable to dimension the facts in the Reseller Sales measure group by Geography because no relationship would exist between Reseller Sales and Geography.

There is no limit to the number of reference dimensions that can be chained together, as shown in the following illustration.

For more information about referenced relationships, see [Define a Referenced Relationship and Referenced Relationship Properties](#).

Fact Dimension Relationships

Fact dimensions, frequently referred to as degenerate dimensions, are standard dimensions that are constructed from attribute columns in fact tables instead of from attribute columns in dimension tables. Useful dimensional data is sometimes stored in a fact table to reduce duplication. For example, the following diagram displays the **FactResellerSales** fact table, from the Adventure Works DW Multidimensional 2012 sample database.

FactResellerSales (dbo.FactResellerSales)
SalesOrderNumber
SalesOrderLineNumber
ProductKey
OrderDateKey
DueDateKey
ShipDateKey
ResellerKey
EmployeeKey
PromotionKey
CurrencyKey
SalesTerritoryKey
RevisionNumber
OrderQuantity
UnitPrice
ExtendedAmount
UnitPriceDiscountPct
DiscountAmount
ProductStandardCost
TotalProductCost
SalesAmount
TaxAmt
Freight
CarrierTrackingNumber
CustomerPONumber

The table contains attribute information not only for each line of an order issued by a reseller, but about the order itself. The attributes circled in the previous diagram identify the information in the **FactResellerSales** table that could be used as attributes in a dimension. In this case, two additional pieces of information, the carrier tracking number

and the purchase order number issued by the reseller, are represented by the CarrierTrackingNumber and CustomerPONumber attribute columns. This information is interesting—for example, users would definitely be interested in seeing aggregated information, such as the total product cost, for all the orders being shipped under a single tracking number. But, without a dimension data for these two attributes cannot be organized or aggregated.

In theory, you could create a dimension table that uses the same key information as the FactResellerSales table and move the other two attribute columns, CarrierTrackingNumber and CustomerPONumber, to that dimension table. However, you would be duplicating a significant portion of data and adding unnecessary complexity to the data warehouse to represent just two attributes as a separate dimension.

 **Note**

Fact dimensions are frequently used to support drillthrough actions. For more information about actions, see [Actions \(Analysis Services - Multidimensional Data\)](#).

 **Note**

Fact dimensions must be incrementally updated after every update to the measure group that is referenced by the fact relationship. If the fact dimension is a ROLAP dimension, the SQL Server Analysis Services processing engine drops any caches and incrementally processes the measure group.

For more information about fact relationships, see [Define a Fact Relationship and Fact Relationship Properties](#).

Many to Many Dimension Relationships

In most dimensions, each fact joins to one and only one dimension member, and a single dimension member can be associated with multiple facts. In relational database terminology, this is referred to as a one-to-many relationship. However, it is frequently useful to join a single fact to multiple dimension members. For example, a bank customer might have multiple accounts (checking, saving, credit card, and investment accounts), and an account can also have joint or multiple owners. The Customer dimension constructed from such relationships would then have multiple members that relate to a single account transaction.

SQL Server Analysis Services lets you define a many-to-many relationship between a dimension and a fact table.

Note

To support a many-to-many dimension relationship, the data source view must have established a foreign key relationship between all the tables involved, as shown in the previous diagram. Otherwise, you will be unable to select the correct intermediate measure group when establishing the relationship in the **Dimension Usage** tab of Dimension Designer.

For more information about many-to-many relationships, see [Define a Many-to-Many Relationship](#) and [Many-to-Many Relationship Properties](#).

Partitions - Partition Storage Modes and Processing

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The storage mode of a partition affects the query and processing performance, storage requirements, and storage locations of the partition and its parent measure group and cube. The choice of storage mode also affects processing choices.

A partition can use one of three basic storage modes:

- Multidimensional OLAP (MOLAP)
- Relational OLAP (ROLAP)
- Hybrid OLAP (HOLAP)

Microsoft SQL Server SQL Server Analysis Services supports all three basic storage modes. It also supports proactive caching, which enables you to combine the characteristics of ROLAP and MOLAP storage for both immediacy of data and query performance. For more information, see [Proactive Caching \(Partitions\)](#).

MOLAP

The MOLAP storage mode causes the aggregations of the partition and a copy of its source data to be stored in a multidimensional structure in SQL Server Analysis Services when the partition is processed. This MOLAP structure is highly optimized to maximize query performance. The storage location can be on the computer where the partition is defined or on another computer running SQL Server Analysis Services. Because a copy of the source data resides in the multidimensional structure, queries can be resolved without accessing the partition's source data. Query response times can be decreased substantially by using aggregations. The data in the partition's MOLAP structure is only as current as the most recent processing of the partition.

As the source data changes, objects in MOLAP storage must be processed periodically to incorporate those changes and make them available to users. Processing updates the data in the MOLAP structure, either fully or incrementally. The time between one processing and the next creates a latency period during which data in OLAP objects may not match the source data. You can incrementally or fully update objects in MOLAP

storage without taking the partition or cube offline. However, there are situations that may require you to take a cube offline to process certain structural changes to OLAP objects. You can minimize the downtime required to update MOLAP storage by updating and processing cubes on a staging server and using database synchronization to copy the processed objects to the production server. You can also use proactive caching to minimize latency and maximize availability while retaining much of the performance advantage of MOLAP storage. For more information, see [Proactive Caching \(Partitions\)](#), [Synchronize Analysis Services Databases](#), and [Processing a multidimensional model \(Analysis Services\)](#).

ROLAP

The ROLAP storage mode causes the aggregations of the partition to be stored in indexed views in the relational database that was specified in the partition's data source. Unlike the MOLAP storage mode, ROLAP does not cause a copy of the source data to be stored in the SQL Server Analysis Services data folders. Instead, when results cannot be derived from the query cache, the indexed views in the data source is accessed to answer queries. Query response is generally slower with ROLAP storage than with the MOLAP or HOLAP storage modes. Processing time is also typically slower with ROLAP. However, ROLAP enables users to view data in real time and can save storage space when you are working with large datasets that are infrequently queried, such as purely historical data.

 **Note**

When using ROLAP, SQL Server Analysis Services may return incorrect information related to the unknown member if a join is combined with a GROUP BY clause. SQL Server Analysis Services eliminates relational integrity errors instead of returning the unknown member value.

If a partition uses the ROLAP storage mode and its source data is stored in SQL Server Database Engine, SQL Server Analysis Services tries to create indexed views to contain aggregations of the partition. If SQL Server Analysis Services cannot create indexed views, it does not create aggregation tables. Although SQL Server Analysis Services handles the session requirements for creating indexed views on SQL Server Database Engine, the following conditions must be met by the ROLAP partition and the tables in its schema in order for SQL Server Analysis Services to create indexed views for aggregations:

- The partition cannot contain measures that use the **Min** or **Max** aggregate functions.
- Each table in the schema of the ROLAP partition must be used only one time. For example, the schema cannot contain [dbo].[address] AS "Customer Address" and [dbo].[address] AS "SalesRep Address".
- Each table must be a table, not a view.
- All table names in the partition's schema must be qualified with the owner name, for example, [dbo].[customer].
- All tables in the partition's schema must have the same owner; for example, you cannot have a FROM clause that references the tables [tk].[customer], [john].[store], and [dave].[sales_fact_2004].
- The source columns of the partition's measures must not be nullable.
- All tables used in the view must have been created with the following options set to ON:
 - ANSI_NULLS
 - QUOTED_IDENTIFIER
- The total size of the index key, in SQL Server Database Engine, cannot exceed 900 bytes. SQL Server Database Engine will assert this condition based on the fixed length key columns when the CREATE INDEX statement is processed. However, if there are variable length columns in the index key, SQL Server Database Engine will also assert this condition for every update to the base tables. Because different aggregations have different view definitions, ROLAP processing using indexed views can succeed or fail depending on the aggregation design.
- The session creating the indexed view must have the following options set to ON: ARITHABORT, CONCAT_NULL_YIELDS_NULL, QUOTED_IDENTIFIER, ANSI_NULLS, ANSI_PADDING, and ANSI_WARNINGS. This setting can be made in SQL Server Management Studio.
- The session creating the indexed view must have the following option set to OFF: NUMERIC_ROUNDABORT. This setting can be made in SQL Server Management Studio.

HOLAP

The HOLAP storage mode combines attributes of both MOLAP and ROLAP. Like MOLAP, HOLAP causes the aggregations of the partition to be stored in a multidimensional structure in an SQL Server SQL Server Analysis Services instance. HOLAP does not cause a copy of the source data to be stored. For queries that access only summary data in the aggregations of a partition, HOLAP is the equivalent of MOLAP. Queries that access source data—for example, if you want to drill down to an atomic cube cell for which there is no aggregation data—must retrieve data from the relational database and will not be as fast as they would be if the source data were stored in the MOLAP structure. With HOLAP storage mode, users will typically experience substantial differences in query times depending upon whether the query can be resolved from cache or aggregations versus from the source data itself.

Partitions stored as HOLAP are smaller than the equivalent MOLAP partitions because they do not contain source data and respond faster than ROLAP partitions for queries involving summary data. HOLAP storage mode is generally suited for partitions in cubes that require rapid query response for summaries based on a large amount of source data. However, where users generate queries that must touch leaf level data, such as for calculating median values, MOLAP is generally a better choice.

Partitions - Proactive Caching

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Proactive caching provides automatic MOLAP cache creation and management for OLAP objects. The cubes immediately incorporate changes that are made to the data in the database, based upon notifications received from the database. The goal of proactive caching is to provide the performance of traditional MOLAP, while retaining the immediacy and ease of management offered by ROLAP.

A simple [ProactiveCaching](#) object is composed of: timing specification, and table notification. The timing specification defines the timeframe for updating the cache after a change notification has been received. The table notification defines the notification schema between the data table and the [ProactiveCaching](#) object.

Multidimensional OLAP (MOLAP) storage provides the best query response, but with a penalty of some data latency. Real-time relational OLAP (ROLAP) storage lets users immediately browse the most recent changes in a data source, but at the penalty of significantly poorer performance than multidimensional OLAP (MOLAP) storage because of the absence of precalculated summaries of data and because relational storage is not optimized for OLAP-style queries. If you have applications in which your users need to see recent data and you also want the performance advantages of MOLAP storage, SQL Server Analysis Services offers the option of proactive caching to address this scenario, particularly in combination with the use of partitions. Proactive caching is set on a per partition and per dimension basis. Proactive caching options can provide a balance between the enhanced performance of MOLAP storage and the immediacy of ROLAP storage, and provide automatic partition processing when underlying data changes or on a set schedule.

Proactive Caching Configuration Options

SQL Server Analysis Services provides several proactive caching configuration options that enable you to maximize performance, minimize latency, and schedule processing. Proactive caching features simplify the process of managing data obsolescence. The proactive caching settings determine how frequently the multidimensional OLAP structure, also called the MOLAP cache, is rebuilt, whether the outdated MOLAP storage is queried while the cache is rebuilt or the underlying ROLAP data source, and whether the cache is rebuilt on a schedule or based on changes in the database.

Minimizing Latency

With proactive caching set to minimize latency, user queries against an OLAP object are made against either ROLAP storage or MOLAP storage, depending whether recent changes have occurred to the data and how proactive caching is configured. The query engine directs queries against source data in MOLAP storage until changes occur in the data source. To minimize latency, after changes occur in a data source, cached MOLAP objects can be dropped and querying switched to ROLAP storage while the MOLAP objects are rebuilt in cache. After the MOLAP objects are rebuilt and processed, queries are automatically switched to the MOLAP storage. The cache refresh can occur extremely quickly for a small partition, such as the current partition - which can be as small as the current day.

Maximizing Performance

To maximize performance while also reducing latency, caching can also be used without dropping the current MOLAP objects. Queries then continue against the MOLAP objects while data is read into and processed in a new cache. This method provides better performance but may result in queries returning old data while the new cache is being built.

Partitions - Remote Partitions

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The data of a remote partition is stored on a different instance of Microsoft SQL Server SQL Server Analysis Services than the instance that contains the definitions (metadata) of the partition and its parent cube. A remote partition is administered on the same instance of SQL Server Analysis Services where the partition and its parent cube are defined.

Note

To store a remote partition, the computer must have an instance of SQL ServerSQL Server Analysis Services installed and be running the same service pack level as the instance where the partition was defined. Remote partitions on instances of an earlier version of SQL Server Analysis Services are not supported.

When remote partitions are included in a measure group, the memory and CPU utilization of the cube is distributed across all the partitions in the measure group. For example, when a remote partition is processed, either alone or as part of parent cube processing, most of the memory and CPU utilization for that partition occurs on the remote instance of SQL Server Analysis Services.

Note

A cube that contains remote partitions can contain write-enabled dimensions; however, this may affect performance for the cube. For more information about write-enabled dimensions, see [Write-Enabled Dimensions](#).

Storage Modes for Remote Partitions

Remote partitions may use any of the storage types used by local partitions: multidimensional OLAP (MOLAP), hybrid OLAP (HOLAP), or relational OLAP (ROLAP). Remote partitions may also use proactive caching. Depending on the storage mode of a remote partition, the following data is stored on the remote instance of SQL Server Analysis Services.

Storage Type	Data
MOLAP	The partition's aggregations and a copy of the partition's source data
HOLAP	The partitions aggregations
ROLAP	No partition data

If a measure group contains multiple MOLAP or HOLAP partitions stored on multiple instances of SQL Server Analysis Services, the cube distributes the data in the measure group data among those instances of SQL Server Analysis Services.

Merging Remote Partitions

Remote partitions can be merged only with other remote partitions that are stored on the same remote instance of SQL Server Analysis Services. For more information about merging partitions, see [Merge Partitions in Analysis Services \(SSAS - Multidimensional\)](#).

Archiving and Restoring Remote Partitions

Data in remote partitions can be archived or restored when the database that stores the remote partition is archived or restored. If you restore a database without restoring a remote partition, you must process the remote partition before you can use the data in the partition. For more information about archiving and restoring databases, see [Backup and Restore of Analysis Services Databases](#).

Partitions - Write-Enabled Partitions

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The data in a cube is generally read-only. However, for certain scenarios, you may want to write-enable a partition. Write-enabled partitions are used to enable business users to explore scenarios by changing cell values and analyzing the effects of the changes on cube data. When you write-enable a partition, client applications can record changes to the data in the partition. These changes, known as writeback data, are stored in a separate table and do not overwrite any existing data in a measure group. However, they are incorporated into query results as if they are part of the cube data.

You can write-enable an entire cube or only certain partitions in the cube. Write-enabled dimensions are different but complementary. A write-enabled partition lets users update partition cells, whereas a write-enabled dimension lets users update dimension members. You can also use these two features in combination. For example, a write-enabled cube or a write-enabled partition does not have to include any write-enabled dimensions. Related topic:[Write-Enabled Dimensions](#).

Note

If you want to write-enable a cube that has a Microsoft Access database as a data source, do not use Microsoft OLE DB Provider for ODBC Drivers in the data source definitions for the cube, its partitions, or its dimensions. Instead, you can use Microsoft Jet 4.0 OLE DB Provider, or any version of the Jet Service Pack that includes Jet 4.0 OLE. For more information, see the Microsoft Knowledge Base article [How to obtain the latest service pack for the Microsoft Jet 4.0 Database Engine](#).

A cube can be write-enabled only if all its measures use the **Sum** aggregate function. Linked measure groups and local cubes cannot be write-enabled.

Writeback Storage

Any change made by the business user is stored in the writeback table as a difference from the currently displayed value. For example, if an end user changes a cell value from 90 to 100, the value **+10** is stored in the writeback table, together with the time of the change and information about the business user who made it. The net effect of

accumulated changes is displayed to client applications. The original value in the cube is preserved, and an audit trail of changes is recorded in the writeback table.

Changes to leaf and nonleaf cells are handled differently. A leaf cell represents an intersection of a measure and a leaf member from every dimension referenced by the measure group. The value of a leaf cell is taken directly from the fact table, and cannot be divided further by drilling down. If a cube or any partition is write-enabled, changes can be made to a leaf cell. Changes can be made to a nonleaf cell only if the client application provides a way of distributing the changes among the leaf cells that make up the nonleaf cell. This process, called allocation, is managed through the UPDATE CUBE statement in Multidimensional Expressions (MDX). Business intelligence developers can use the UPDATE CUBE statement to include allocation functionality. For more information, see [UPDATE CUBE Statement \(MDX\)](#).

Important

When updated cells do not overlap, the **Update Isolation Level** connection string property can be used to enhance performance for UPDATE CUBE. For more information, see [ConnectionString](#).

Regardless of whether a client application distributes changes that were made to nonleaf cells, whenever queries are evaluated, changes in the writeback table are applied to both leaf and nonleaf cells so that business users can view the effects of the changes throughout the cube.

Changes that were made by the business user are kept in a separate writeback table that you can work with as follows:

- Convert to a partition to permanently incorporate changes into the cube. This action makes the measure group read-only. You can specify a filter expression to select the changes you want to convert.
- Discard to return the partition to its original state. This action makes the partition read-only.

Security

A business user is permitted to record changes in a cube's writeback table only if the business user belongs to a role that has read/write permission to the cube's cells. For each role, you can control which cube cells can and cannot be updated. For more information, see [Grant cube or model permissions \(Analysis Services\)](#).

Partitions (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A partition is a container for a portion of the measure group data. Partitions are not seen from MDX queries; all queries reflect the whole content of the measure group, regardless of how many partitions are defined for the measure group. The data content of a partition is defined by the query bindings of the partition, and by the slicing expression.

A simple [Partition](#) object is composed of: basic information, slicing definition, aggregation design, and others. Basic information includes the name of the partition, the storage mode, the processing mode, and others. The slicing definition is an MDX expression specifying a tuple or a set. The slicing definition has the same restrictions as the StrToSet MDX function. Together with the CONSTRAINED parameter, the slicing definition can use dimension, hierarchy, level and member names, keys, unique names, or other named objects in the cube, but cannot use MDX functions. The aggregation design is a collection of aggregation definitions that can be shared across multiple partitions. The default is taken from the parent cube's aggregation design.

Partitions are used by Microsoft SQL Server SQL Server Analysis Services to manage and store data and aggregations for a measure group in a cube. Every measure group has at least one partition; this partition is created when the measure group is defined. When you create a new partition for a measure group, the new partition is added to the set of partitions that already exist for the measure group. The measure group reflects the combined data that is contained in all its partitions. This means that you must ensure that the data for a partition in a measure group is exclusive of the data for any other partition in the measure group to ensure that data is not reflected in the measure group more than once. The original partition for a measure group is based on a single fact table in the data source view of the cube. When there are multiple partitions for a measure group, each partition can reference a different table in either the data source view or in the underlying relational data source for the cube. More than one partition in a measure group can reference the same table, if each partition is restricted to different rows in the table.

Partitions are a powerful and flexible means of managing cubes, especially large cubes. For example, a cube that contains sales information can contain a partition for the data

of each past year and also partitions for each quarter of the current year. Only the current quarter partition needs to be processed when current information is added to the cube; processing a smaller amount of data will improve processing performance by decreasing processing time. At the end of the year the four quarterly partitions can be merged into a single partition for the year and a new partition created for the first quarter of the new year. Further, this new partition creation process can be automated as part of your data warehouse loading and cube processing procedures.

Partitions are not visible to business users of the cube. However, administrators can configure, add, or drop partitions. Each partition is stored in a separate set of files. The aggregate data of each partition can be stored on the instance of SQL Server Analysis Services where the partition is defined, on another instance of SQL Server Analysis Services, or in the data source that is used to supply the partition's source data. Partitions allow the source data and aggregate data of a cube to be distributed across multiple hard drives and among multiple server computers. For a cube of moderate to large size, partitions can greatly improve query performance, load performance, and ease of cube maintenance.

The storage mode of each partition can be configured independently of other partitions in the measure group. Partitions can be stored by using any combination of options for source data location, storage mode, proactive caching, and aggregation design. Options for real-time OLAP and proactive caching let you balance query speed against latency when you design a partition. Storage options can also be applied to related dimensions and to facts in a measure group. This flexibility lets you design cube storage strategies appropriate to your needs. For more information, see [Partition Storage Modes and Processing, Aggregations and Aggregation Designs](#) and [Proactive Caching \(Partitions\)](#).

Partition Structure

The structure of a partition must match the structure of its measure group, which means that the measures that define the measure group must also be defined in the partition, along with all related dimensions. Therefore, when a partition is created, it automatically inherits the same set of measures and related dimensions that were defined for the measure group.

However, each partition in a measure group can have a different fact table, and these fact tables can be from different data sources. When different partitions in a measure group have different fact tables, the tables must be sufficiently similar to maintain the structure of the measure group, which means that the processing query returns the same columns and same data types for all fact tables for all partitions.

When fact tables for different partitions are from different data sources, the source tables for any related dimensions, and also any intermediate fact tables, must also be present in all data sources and must have the same structure in all the databases. Also, all dimension table columns that are used to define attributes for cube dimensions related to the measure group must be present in all of the data sources. There is no need to define all the joins between the source table of a partition and a related dimension table if the partition source table has the identical structure as the source table for the measure group.

Columns that are not used to define measures in the measure group can be present in some fact tables but absent in others. Similarly, columns that are not used to define attributes in related dimension tables can be present in some databases but absent in others. Tables that are not used for either fact tables or related dimension tables can be present in some databases but absent in others.

Data Sources and Partition Storage

A partition is based either on a table or view in a data source, or on a table or named query in a data source view. The location where partition data is stored is defined by the data source binding. You can partition a measure group using either a single-table partition scheme, or a multi-table partition scheme:

- In a multi-table partition scheme each partition in a measure group partition is based on a separate table. This kind of partitioning is appropriate when data is separated into multiple tables. For example, some relational databases have a separate table for each month's data.
- In a single-table partition scheme a measure group is based on a single table, and each partition is based on a source system query that filters the data for the partition. For example, if a single table contains several months data, the measure group could still be partitioned by month by applying a Transact-SQL WHERE clause that returns a separate month's data for each partition.

Each partition has storage settings that determine whether the data and aggregations for the partition are stored in the local instance of SQL Server Analysis Services or in a remote partition using another instance of SQL Server Analysis Services. The storage settings can also specify the storage mode and whether proactive caching is used to control latency for a partition. For more information, see [Partition Storage Modes and Processing](#), [Proactive Caching \(Partitions\)](#), and [Remote Partitions](#).

Incremental Updates

When you create and manage partitions in multiple-partition measure groups, you must take special precautions to guarantee that cube data is accurate. Although these precautions do not usually apply to single-partition measure groups, they do apply when you incrementally update partitions. When you incrementally update a partition, a new temporary partition is created that has a structure identical to that of the source partition. The temporary partition is processed and then merged with the source partition. Therefore, you must ensure that the processing query that populates the temporary partition does not duplicate any data already present in an existing partition.

Perspectives

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A perspective is a definition that allows users to see a cube in a simpler way. A perspective is a subset of the features of a cube. A perspective enables administrators to create views of a cube, helping users to focus on the most relevant data for them. A perspective contains subsets of all objects from a cube. A perspective cannot include elements that are not defined in the parent cube.

A simple [Perspective](#) object is composed of: basic information, dimensions, measure groups, calculations, KPIs, and actions. Basic information includes the name and the default measure of the perspective. The dimensions are a subset of the cube dimensions. The measure groups are a subset of the cube measure groups. The calculations are a subset of the cube calculations. The KPIs are a subset of the cube KPIs. The actions are a subset of the cube actions.

A cube has to be updated and processed before the perspective can be used.

Cubes can be very complex objects for users to explore in Microsoft SQL Server SQL Server Analysis Services. A single cube can represent the contents of a complete data warehouse, with multiple measure groups in a cube representing multiple fact tables, and multiple dimensions based on multiple dimension tables. Such a cube can be very complex and powerful, but daunting to users who may only need to interact with a small part of the cube in order to satisfy their business intelligence and reporting requirements.

In Microsoft SQL Server SQL Server Analysis Services, you can use a perspective to reduce the perceived complexity of a cube in SQL Server Analysis Services. A perspective defines a viewable subset of a cube that provides focused, business-specific or application-specific viewpoints on the cube. The perspective controls the visibility of objects that are contained by a cube. The following objects can be displayed or hidden in a perspective:

- Dimensions
- Attributes
- Hierarchies
- Measure groups

- Measures
- Key Performance Indicators (KPIs)
- Calculations (calculated members, named sets, and script commands)
- Actions

For example, the **Adventure Works** cube in the Adventure Works DW Multidimensional 2012 sample SQL Server Analysis Services database contains eleven measure groups and twenty-one different cube dimensions, representing sales, sales forecasting, and financial data. A client application can directly reference the complete cube, but this viewpoint may be overwhelming to a user trying to extract basic sales forecasting information. Instead, the same user can use the **Sales Targets** perspective to limit the view of the **Adventure Works** cube to only those objects relevant to sales forecasting.

Objects in a cube that are not visible to the user through a perspective can still be directly referenced and retrieved using XML for Analysis (XMLA), Multidimensional Expressions (MDX), or Data Mining Extensions (DMX) statements. Perspectives do not restrict access to objects in a cube and should not be used as such; instead, perspectives are used to provide a better user experience while accessing a cube.

A perspective is a read-only view of the cube; objects in the cube cannot be renamed or changed by using a perspective. Similarly, the behavior or features of a cube, such as the use of visual totals, cannot be changed by using a perspective.

Security

Perspectives are not meant to be used as a security mechanism, but as a tool for providing a better user experience in business intelligence applications. All security for a particular perspective is inherited from the underlying cube. For example, perspectives cannot provide access to objects in a cube to which a user does not already have access.

- Security for the cube must be resolved before access to objects in the cube can be provided through a perspective.

Logical Architecture Overview (Analysis Services - Multidimensional Data)

Article • 12/09/2022

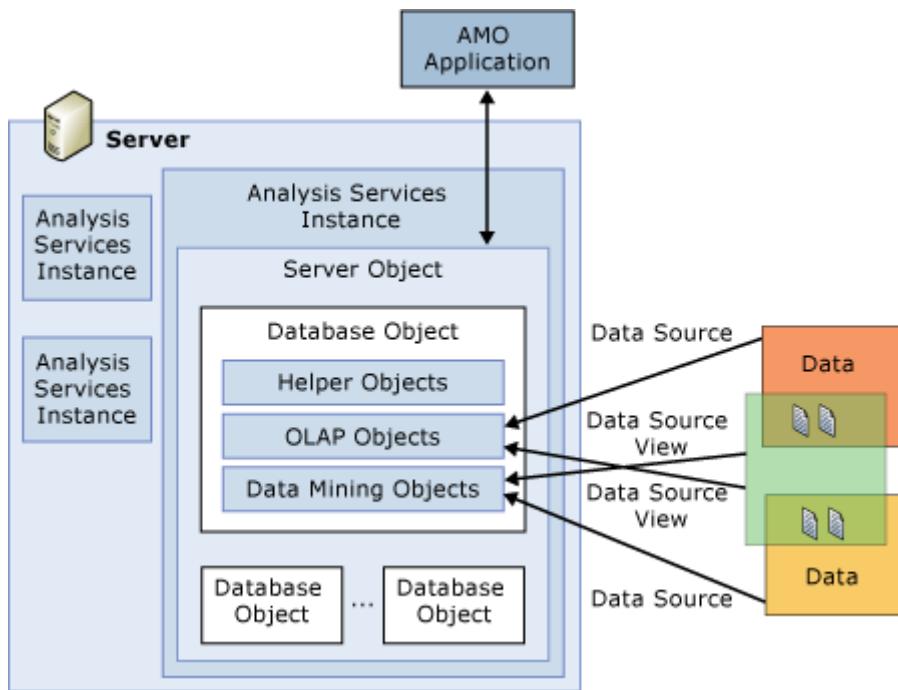

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Analysis Services operates in a server deployment mode that determines the memory architecture and runtime environment used by different types of Analysis Services models. Server mode is determined during installation. **Multidimensional and Data Mining mode** supports traditional OLAP and data mining. **Tabular mode** supports tabular models. **SharePoint integrated mode** refers to an instance of Analysis Services that was installed as Power Pivot for SharePoint, used for loading and querying Excel or Power Pivot data models inside a workbook.

This topic explains the basic architecture of Analysis Services when operating in Multidimensional and Data Mining mode. For more information about other modes, see [Tabular Modeling](#) and [Comparing Tabular and Multidimensional Solutions](#).

Basic Architecture

An instance of SQL Server Analysis Services can contain multiple databases, and a database can have OLAP objects and data mining objects at the same time. Applications connect to a specified instance of SQL Server Analysis Services and a specified database. A server computer can host multiple instances of SQL Server Analysis Services. Instances of SQL Server Analysis Services are named as "<ServerName>\<InstanceName>". The following illustration shows all mentioned relationships between SQL Server Analysis Services objects.

Basic classes are the minimum set of objects that are required to build a cube. This minimum set of objects is a dimension, a measure group, and a partition. An aggregation is optional.

Dimensions are built from attributes and hierarchies. Hierarchies are formed by an ordered set of attributes, where each attribute of the set corresponds to a level in the hierarchy.

Cubes are built from dimensions and measure groups. The dimensions in the dimensions collection of a cube belong to the dimensions collection of the database. Measure groups are collections of measures that have the same data source view and have the same subset of dimensions from the cube. A measure group has one or more partitions to manage the physical data. A measure group can have a default aggregation design. The default aggregation design can be used by all partitions in the measure group; also, each partition can have its own aggregation design.

Server Objects

Each instance of SQL Server Analysis Services is seen as a different server object in AMO; each different instance is connected to a [Server](#) object by a different connection. Each server object contains one or more data sources, data source views, and database objects, as well as assemblies and security roles.

Dimension Objects

Each database object contains multiple dimension objects. Each dimension object contains one or more attributes, which are organized into hierarchies.

Cube Objects

Each database object contains one or more cube objects. A cube is defined by its

measures and dimensions. The measures and dimensions in a cube are derived from the tables and views in the data source view on which the cube is based, or which is generated from the measure and dimension definitions.

Object Inheritance

The ASSL object model contains many repeated element groups. For example, the element group, "Dimensions contain Hierarchies," defines the dimension hierarchy of an element. Both **Cubes** and **MeasureGroups** contain the element group, "Dimensions contain Hierarchies."

Unless explicitly overridden, an element inherits the details of these repeated element groups from the higher level. For example, the **Translations** for a **CubeDimension** are the same as the **Translations** for its ancestor element, **Cube**.

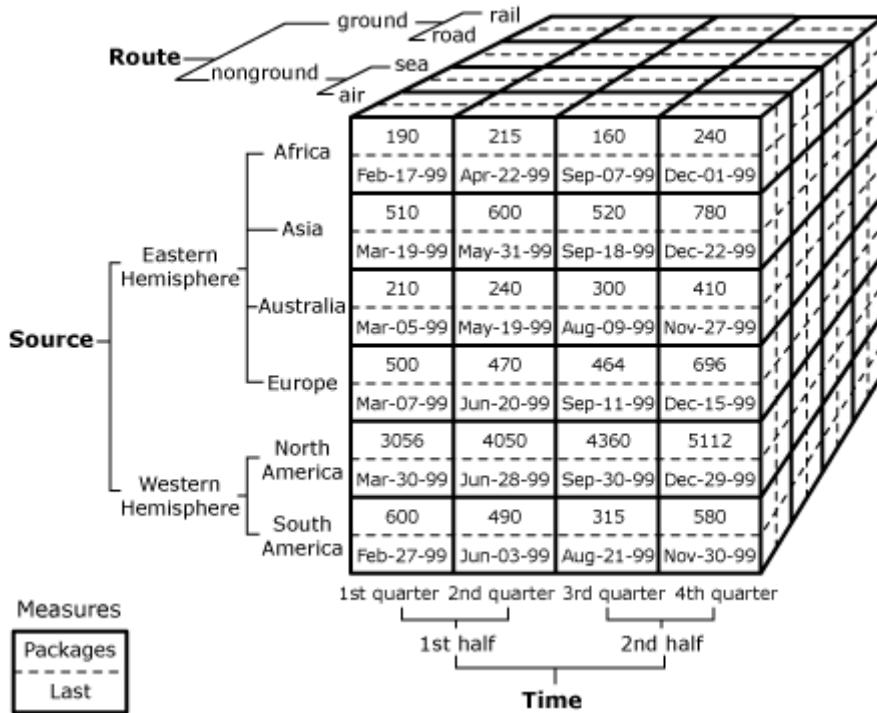

To explicitly override properties inherited from a higher-level object, an object does not need to repeat explicitly the entire structure and properties of the higher-level object. The only properties that an object needs to state explicitly are those properties that the object wants to override. For example, a **CubeDimension** may list only those **Hierarchies** that need to be disabled in the **Cube**, or for which the visibility needs to be changed, or for which some **Level** details have not been provided at the **Dimension** level.

Some properties specified on an object provide default values for the same property on a child or descendant object. For example, **Cube.StorageMode** provides the default value for **Partition.StorageMode**. For inherited default values, ASSL applies these rules for inherited default values:

- When the property for the child object is null in the XML, the property's value defaults to the inherited value. However, if you query the value from the server, the server returns the null value of the XML element.
- It is not possible to determine programmatically whether the property of a child object has been set directly on the child object or inherited.

Example

The Imports cube contains two measures, Packages and Last, and three related dimensions, Route, Source, and Time.

The smaller alphanumeric values around the cube are the members of the dimensions. Example members are ground (member of the Route dimension), Africa (member of the Source dimension), and 1st quarter (member of the Time dimension).

Measures

The values within the cube cells represent the two measures, Packages and Last. The Packages measure represents the number of imported packages, and the **Sum** function is used to aggregate the facts. The Last measure represents the date of receipt, and the **Max** function is used to aggregate the facts.

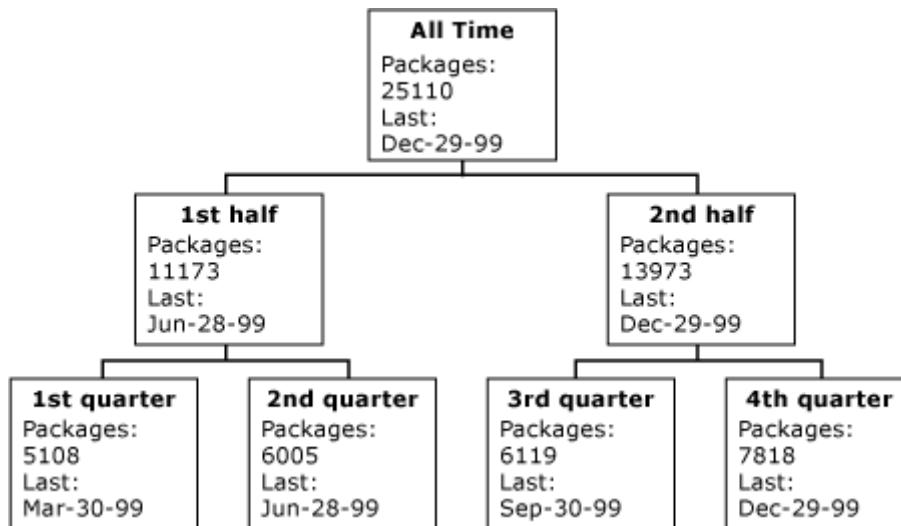

Dimensions

The Route dimension represents the means by which the imports reach their destination. Members of this dimension include ground, nonground, air, sea, road, or rail. The Source dimension represents the locations where the imports are produced, such as Africa or Asia. The Time dimension represents the quarters and halves of a single year.

Aggregates

Business users of a cube can determine the value of any measure for each member of every dimension, regardless of the level of the member within the dimension, because SQL Server Analysis Services aggregates values at upper levels as needed. For example, the measure values in the preceding illustration can be aggregated according to a

standard calendar hierarchy by using the Calendar Time hierarchy in the Time dimension as illustrated in the following diagram.

In addition to aggregating measures by using a single dimension, you can aggregate measures by using combinations of members from different dimensions. This allows business users to evaluate measures in multiple dimensions simultaneously. For example, if a business user wants to analyze quarterly imports that arrived by air from the Eastern Hemisphere and Western Hemisphere, the business user can issue a query on the cube to retrieve the following dataset.

Packages | Time Frame | All Sources | Eastern Hemisphere | Western Hemisphere | | -----
----- | ----- | ----- | ----- |

All Time	25110	6547	18563		
1st Half	11173	2977	8196		
1st quarter	5108	1452	3656		
2nd quarter	6065	1525	4540	Jun-28-99	Jun-20-99
2nd Half	13937	3570	10367	Dec-29-99	Dec-22-99
3rd quarter	6119	1444	4675	Sep-30-99	Sep-18-99
4th quarter	7818	2126	5692	Dec-29-99	Dec-22-99

Last | Time Frame | All Sources | Eastern Hemisphere | Western Hemisphere | | -----
----- | ----- | ----- | |All Time|Dec-29-99|Dec-22-99|Dec-29-99|

1st Half	Jun-28-99	Jun-20-99	Jun-28-99		
1st quarter	Mar-30-99	Mar-19-99	Mar-30-99		
2nd quarter	Jun-28-99	Jun-20-99	Jun-28-99		
2nd Half	Dec-29-99	Dec-22-99	Dec-29-99		
3rd quarter	Sep-30-99	Sep-18-99	Sep-30-99		
4th quarter	Dec-29-99	Dec-22-99	Dec-29-99		

After a cube is defined, you can create new aggregations, or you can change existing aggregations to set options such as whether aggregations are precalculated during processing or calculated at query time. [Related topic:Aggregations and Aggregation Designs.](#)

Mapping Measures, Attributes, and Hierarchies

The measures, attributes, and hierarchies in the example cube are derived from the following columns in the cube's fact and dimension tables.

[\[+\] Expand table](#)

Measure or attribute (level)	Members	Source table	Source column	Sample column value
Packages measure	Not applicable	ImportsFactTable	Packages	12
Last measure	Not applicable	ImportsFactTable	Last	May-03-99
Route Category level in Route dimension	nonground,ground	RouteDimensionTable	Route_Category	Nonground
Route attribute in Route dimension	air,sea,road,rail	RouteDimensionTable	Route	Sea
Hemisphere attribute in Source dimension	Eastern Hemisphere,Western Hemisphere	SourceDimensionTable	Hemisphere	Eastern Hemisphere
Continent attribute in Source dimension	Africa,Asia,Australia,Europe,N. America,S. America	SourceDimensionTable	Continent	Europe
Half attribute in Time dimension	1st half,2nd half	TimeDimensionTable	Half	2nd half

Measure or attribute (level)	Members	Source table	Source column	Sample column value
Quarter attribute in Time dimension	1st quarter,2nd quarter,3rd quarter,4th quarter	TimeDimensionTable	Quarter	3rd quarter

Data in a single cube cell is usually derived from multiple rows in the fact table. For example, the cube cell at the intersection of the air member, the Africa member, and the 1st quarter member contains a value that is derived by aggregating the following rows in the **ImportsFactTable** fact table.

[\[+\] Expand table](#)

Import_ReceiptKey	RouteKey	SourceKey	TimeKey	Packages	Last
3516987	1	6	1	15	Jan-10-99
3554790	1	6	1	40	Jan-19-99
3572673	1	6	1	34	Jan-27-99
3600974	1	6	1	45	Feb-02-99
3645541	1	6	1	20	Feb-09-99
3674906	1	6	1	36	Feb-17-99

In the preceding table, each row has the same values for the **RouteKey**, **SourceKey**, and **TimeKey** columns, indicating that these rows contribute to the same cube cell.

The example shown here represents a very simple cube, in that the cube has a single measure group, and all the dimension tables are joined to the fact table in a star schema. Another common schema is a snowflake schema, in which one or more dimension tables join to another dimension table, rather than joining directly to the fact table. [Related topic:Dimensions \(Analysis Services - Multidimensional Data\).](#)

The example shown here contains only a single fact table. When a cube has multiple fact tables, the measures from each fact table are organized into measure groups, and a measure group is related to a specific set of dimensions by defined dimension relationships. These relationships are defined by specifying the participating tables in the data source view and the granularity of the relationship. [Related topic:Dimension Relationships.](#)

Security Roles (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Roles are used in Microsoft SQL Server SQL Server Analysis Services to manage security for SQL Server Analysis Services objects and data. In basic terms, a role associates the security identifiers (SIDs) of Microsoft Windows users and groups that have specific access rights and permissions defined for objects managed by an instance of SQL Server Analysis Services. Two types of roles are provided in SQL Server Analysis Services:

- The server role, a fixed role that provides administrator access to an instance of SQL Server Analysis Services.
- Database roles, roles defined by administrators to control access to objects and data for non-administrator users.

Security in Microsoft SQL Server SQL Server Analysis Services security is managed by using roles and permissions. Roles are groups of users. Users, also called members, can be added or removed from roles. Permissions for objects are specified by roles, and all members in a role can use the objects for which the role has permissions. All members in a role have equal permissions to the objects. Permissions are particular to objects. Each object has a permissions collection with the permissions granted on that object, different sets of permissions can be granted on an object. Each permission, from the permissions collection of the object, has a single role assigned to it.

Role and Role Member Objects

A role is a containing object for a collection of users (members). A Role definition establishes the membership of the users in SQL Server Analysis Services. Because permissions are assigned by role, a user must be a member of a role before the user has access to any object.

A [Role](#) object is composed of the parameters Name, Id, and Members. Members is a collection of strings. Each member contains the user name in the form of "domain\username". Name is a string that contains the name of the role. ID is a string that contains the unique identifier of the role.

Server Role

The SQL Server Analysis Services server role defines administrative access of Windows users and groups to an instance of SQL Server Analysis Services. Members of this role have access to all SQL Server Analysis Services databases and objects on an instance of SQL Server Analysis Services, and can perform the following tasks:

- Perform server-level administrative functions using SQL Server Management Studio or SQL Server Data Tools, including creating databases and setting server-level properties.
- Perform administrative functions programmatically with Analysis Management Objects (AMO).
- Maintain SQL Server Analysis Services database roles.
- Start traces (other than for processing events, which can be performed by a database role with Process access).

Every instance of SQL Server Analysis Services has a server role that defines which users can administer that instance. The name and ID of this role is Administrators, and unlike database roles, the server role cannot be deleted, nor can permissions be added or removed. In other words, a user either is or is not an administrator for an instance of SQL Server Analysis Services, depending on whether he or she is included in the server role for that instance of SQL Server Analysis Services.

Database Roles

An SQL Server Analysis Services database role defines user access to objects and data in an SQL Server Analysis Services database. A database role is created as a separate object in an SQL Server Analysis Services database, and applies only to the database in which that role is created. Windows users and groups are included in the role by an administrator, who also defines permissions within the role.

The permissions of a role may allow members to access and administer the database, in addition to the objects and data within the database. Each permission has one or more access rights associated with it, which in turn give the permission finer control over access to a particular object in the database.

Permission Objects

Permissions are associated with an object (cube, dimension, others) for a particular role. Permissions specify what operations the member of that role can perform on that object.

The [Permission](#) class is an abstract class. Therefore, you must use the derived classes to define permissions on the corresponding objects. For each object, a permission derived class is defined.

[\[+\] Expand table](#)

Object	Class
Database	DatabasePermission
DataSource	DataSourcePermission
Dimension	DimensionPermission
Cube	CubePermission
MiningStructure	MiningStructurePermission
MiningModel	MiningModelPermission

Possible actions enabled by permissions are shown in the list:

[\[+\] Expand table](#)

Action	Values	Explanation
Process	{true, false} Default=false	If true , members can process the object and any object that is contained in the object. Process permissions do not apply to mining models. MiningModel permissions are always inherited from MiningStructure .
ReadDefinition	{None, Basic, Allowed} Default=None	Specifies whether members can read the data definition (ASSL) associated with the object. If Allowed , members can read the ASSL associated with the object. Basic and Allowed are inherited by objects that are contained in the object. Allowed overrides Basic and None . Allowed is required for DISCOVER_XML_METADATA

Action	Values	Explanation
		on an object. Basic is required to create linked objects and local cubes.
Read	<p>{None, Allowed}</p> <p>Default=None (Except for DimensionPermission, where default=Allowed)</p>	<p>Specifies whether members have read access to schema rowsets and data content.</p> <p>Allowed gives read access on a database, which lets you discover a database.</p> <p>Allowed on a cube gives read access in schema rowsets and access to cube content (unless constrained by CellPermission and CubeDimensionPermission).</p> <p>Allowed on a dimension grants that read permission on all attributes in the dimension (unless constrained by CubeDimensionPermission). Read permission is used for static inheritance to the CubeDimensionPermission only. None on a dimension hides the dimension and gives access to the default member only for aggregatable attributes; an error is raised if the dimension contains a non-aggregatable attribute.</p> <p>Allowed on a MiningModelPermission grants permissions to see objects in schema rowsets and to perform predict joins.</p> <p>NoteAllowed is required to read or write to any object in the database.</p>
Write	<p>{None, Allowed}</p> <p>Default=None</p>	<p>Specifies whether members have write access to data of the parent object.</p> <p>Access applies to Dimension, Cube, and MiningModel subclasses. It does not apply to database MiningStructure subclasses, which generates a validation error.</p> <p>Allowed on a Dimension grants write permission on all attributes in the dimension.</p> <p>Allowed on a Cube grants write permission on the cells of the cube for partitions defined as Type=writeback.</p> <p>Allowed on a MiningModel grants permission to modify model content.</p>

Action	Values	Explanation
		<p>Allowed on a MiningStructure has no specific meaning in SQL Server Analysis Services.</p> <p>Note: Write cannot be set to Allowed unless read is also set to Allowed</p>
Administer Note: Only in Database permissions	{true, false} Default= false	<p>Specifies whether members can administer a database.</p> <p>true grants members access to all objects in a database.</p> <p>A member can have Administer permissions for a specific database, but not for others.</p>

Server Objects (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Introducing Server Objects

The [Server](#) object represents the server and the instance of Microsoft SQL Server SQL Server Analysis Services that you want to work with.

As soon as you have a connected instance of SQL Server Analysis Services, you will be able to see:

- All databases that you can access, as a collection.
- All defined server properties, as a collection.
- The connection string, the connection information, and the session ID.
- The product name, edition, and version.
- The roles collections.
- The traces collection.
- The assemblies collection.

Understanding Microsoft OLAP Logical Architecture

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Microsoft SQL Server SQL Server Analysis Services uses both server and client components to supply online analytical processing (OLAP) and data mining functionality for business intelligence applications:

- The server component of SQL Server Analysis Services is implemented as a Microsoft Windows service. SQL Server SQL Server Analysis Services supports multiple instances on the same computer, with each instance of SQL Server Analysis Services implemented as a separate instance of the Windows service.
- Clients communicate with SQL Server Analysis Services using the public standard XML for Analysis (XMLA), a SOAP-based protocol for issuing commands and receiving responses, exposed as a Web service. Client object models are also provided over XMLA, and can be accessed either by using a managed provider, such as ADOMD.NET, or a native OLE DB provider.
- Query commands can be issued using the following languages: SQL; Multidimensional Expressions (MDX), an industry standard query language for analysis; or Data Mining Extensions (DMX), an industry standard query language oriented toward data mining. Analysis Services Scripting Language (ASSL) can also be used to manage SQL Server Analysis Services database objects.

SQL Server Analysis Services also supports a local cube engine that enables applications on disconnected clients to browse locally stored multidimensional data. For more information, see [Client Architecture Requirements for Analysis Services Development](#)

Client Architecture Requirements for Analysis Services Development

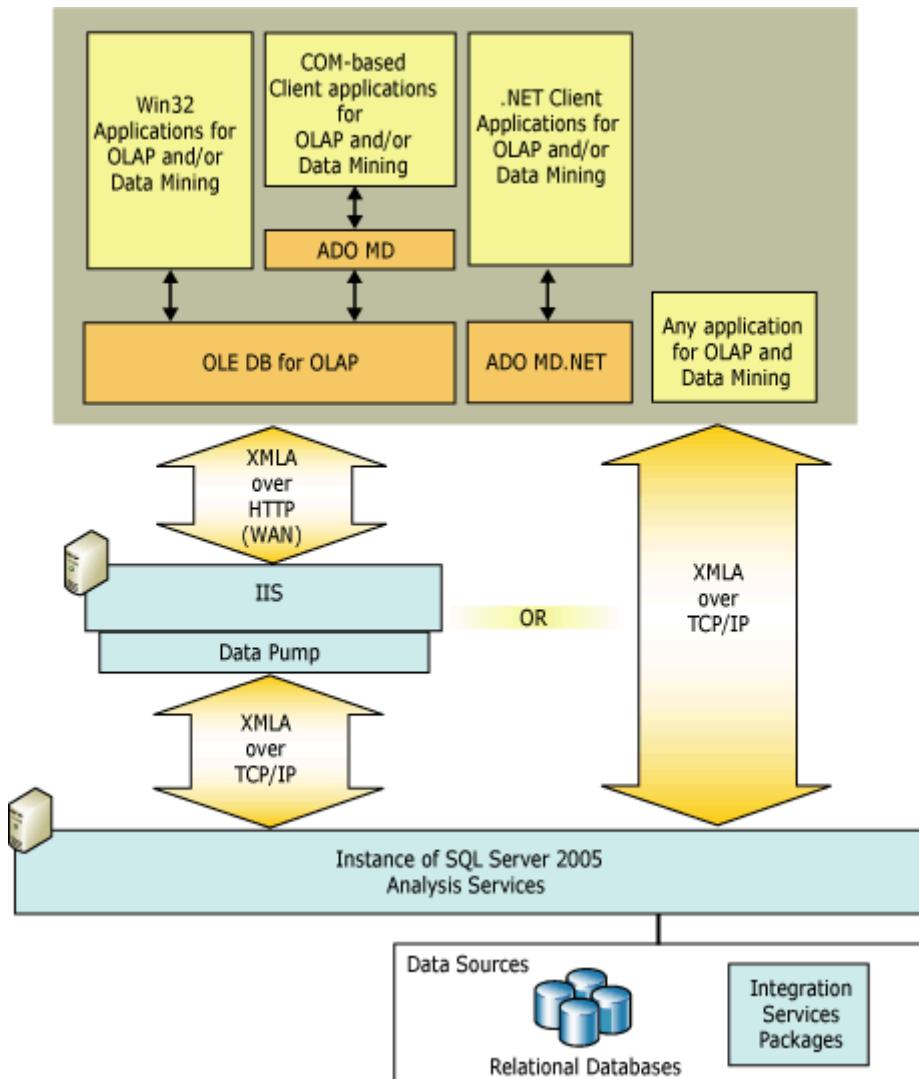

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Microsoft SQL Server SQL Server Analysis Services supports a thin-client architecture. The SQL Server Analysis Services calculation engine is entirely server-based, so all queries are resolved on the server. As a result, only a single round trip between the client and the server is required for each query, resulting in scalable performance as queries increase in complexity.

The native protocol for SQL Server Analysis Services is XML for Analysis (XML/A). SQL Server Analysis Services provides several data access interfaces for client applications, but all of these components communicate with an instance of SQL Server Analysis Services using XML for Analysis.

Several different providers are provided with SQL Server Analysis Services to support different programming languages. A provider communicates with an SQL Server Analysis Services server by sending and receiving XML for Analysis in SOAP packets over TCP/IP or over HTTP through Internet Information Services (IIS). An HTTP connection uses a COM object instantiated by IIS, called a data pump, which acts as a conduit for SQL Server Analysis Services data. The data pump does not examine the underlying data contained in the HTTP stream in any way, nor are any of the underlying data structures available to any of the code in the data library itself.

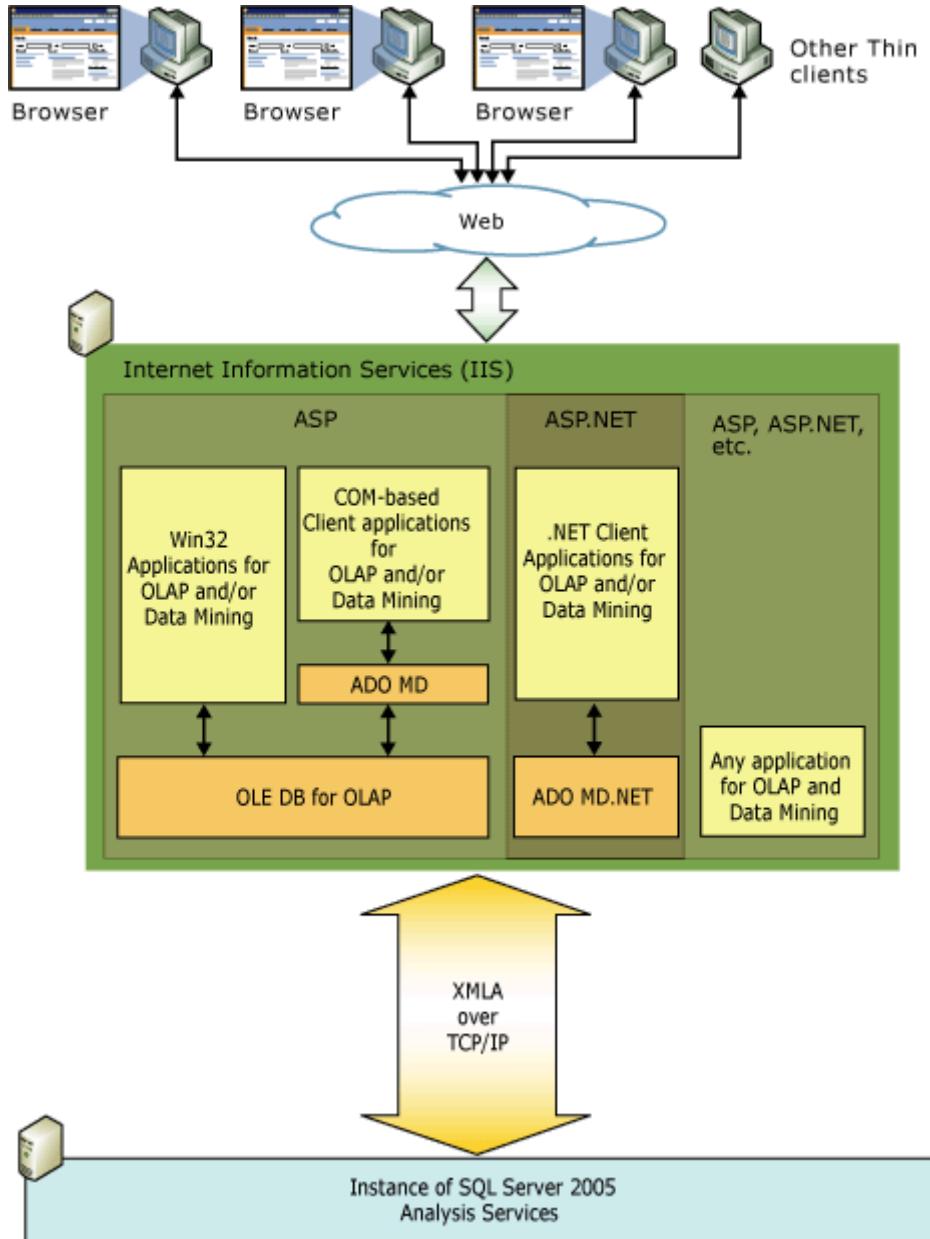

Win32 client applications can connect to an SQL Server Analysis Services server using OLE DB for OLAP interfaces or the Microsoft® ActiveX® Data Objects (ADO) object model for Component Object Model (COM) automation languages, such as Microsoft Visual Basic®. Applications coded with .NET languages can connect to an SQL Server Analysis Services server using ADOMD.NET.

Existing applications can communicate with SQL Server Analysis Services without modification simply by using one of the SQL Server Analysis Services providers.

[\[+\] Expand table](#)

Programming Language	Data Access Interface
C++	OLE DB for OLAP
Visual Basic 6	ADO MD
.NET languages	ADO MD.NET
Any language that supports SOAP	XML for Analysis

SQL Server Analysis Services has a Web architecture with a fully scalable middle tier for deployment by both small and large organizations. SQL Server Analysis Services provides broad middle tier support for Web services. ASP applications are supported by OLE DB for OLAP and ADO MD, ASP.NET applications are supported by ADOMD.NET. The middle tier, illustrated in the following figure, is scalable to many concurrent users.

Both client and middle tier applications can communicate directly with SQL Server Analysis Services without using a provider. Client and middle tier applications may send XML for Analysis in SOAP packets over TCP/IP, HTTP, or HTTPS. The client may be coded using any language that supports SOAP. Communication in this case is most easily managed by Internet Information Services (IIS) using HTTP, although a direct connection to the server using TCP/IP may also be coded. This is the thinnest possible client solution for SQL Server Analysis Services.

Analysis Services in Tabular or SharePoint Mode

In SQL Server 2017, the server can be started in VertiPaq in-memory analytics engine (VertiPaq) mode for tabular databases and for Power Pivot workbooks that have been published to a SharePoint site.

Power Pivot for Excel and SQL Server Data Tools are the only client environments that are supported for creating and querying in-memory databases that use SharePoint or Tabular mode, respectively. The embedded Power Pivot database that you create by using the Excel and Power Pivot tools is contained within the Excel workbook, and is saved as part of the Excel .xlsx file.

However, a Power Pivot workbook can use data that is stored in a traditional cube if you import the cube data into the workbook. You can also import data from another Power Pivot workbook if it has been published to a SharePoint site.

ⓘ Note

When you use a cube as a data source for a Power Pivot workbook, the data that you get from the cube is defined as an MDX query; however, the data is imported as a flattened snapshot. You cannot interactively work with the data or refresh the data from the cube.

Interfaces for Power Pivot Client

Power Pivot interacts with the VertiPaq in-memory analytics engine storage engine within the workbook by using the established interfaces and languages for Analysis Services: AMO and ADOMD.NET, and MDX and XMLA. Within the add-in, measures are defined by using a formula language similar to Excel, Data Analysis Expressions (DAX). DAX expressions are embedded within the XMLA messages that are sent to the in-process server.

Providers

Communications between Power Pivot and Excel use the MSOLAP OLEDB provider (version 11.0). Within the MSOLAP provider, there are four different modules, or transports, that can be used for sending messages between the client and server.

TCP/IP Used for normal client-server connections.

HTTP Used for HTTP connections via the SSAS data pump service, or by a call to the SharePoint Power Pivot Web Service (WS) component.

INPROC Used for connections to the in-process engine.

CHANNEL Reserved for communications with the Power Pivot System Service in the SharePoint farm.

Data Types in Analysis Services

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

For all [DataItem](#) objects, SQL Server Analysis Services supports the following subset of [System.Data.OleDb.OleDbType](#). To set or read the data type, use [DataItem Data Type \(ASSL\)](#).

Supported Data Types

 Expand table

Data Type	Description
BigInt	A 64-bit signed integer. The <i>BigInt</i> value type represents integers with values ranging from negative 9,223,372,036,854,775,808 to positive 9,223,372,036,854,775,807.
Binary	A stream of binary data of Byte type. Byte is a value type that represents unsigned integers with values that range from 0 to 255.
Boolean	Instances of this type have values of either true or false .
Currency	A <i>currency</i> value ranging from -922,337,203,685,477.5808 to +922,337,203,685,477.5807 with accuracy to a ten-thousandth of a currency unit (four decimal places).
Date	Date and time data, stored as a double. The whole portion is the number of days since December 30, 1899, and the fractional portion is a fraction of a day or time of the day.
Double	A floating-point number within the range of -1.79769313486232E +308 to 1.79769313486232E +308. A Double value stores number information up to 15 decimal digits of precision.
Integer	A 32-bit signed integer that represents signed integers with values that range from negative 2,147,483,648 through positive 2,147,483,647.
Single	A floating-point number within the range of - 3.4028235E +38 through 3.4028235E +38. A Single value stores number information up to 7 decimal digits of precision.
Smallint	A 16-bit signed integer. The <i>Smallint</i> value type represents signed integers with values ranging from negative 32768 to positive 32767.

Data Type	Description
Tinyint	An 8-bit signed integer. The <i>Tinyint</i> value type represents integers with values ranging from negative 128 to positive 127.
UnsignedBigInt	A 64-bit unsigned integer. The <i>UnsignedBigInt</i> value type represents unsigned integers with values ranging from 0 to 18,446,744,073,709,551,615.
UnsignedInt	A 32-bit unsigned integer. The <i>UnsignedInt</i> value type represents unsigned integers with values ranging from 0 to 4,294,967,295.
UnsignedSmallInt	A 16-bit unsigned integer. The <i>UnsignedSmallInt</i> value type represents unsigned integers with values ranging from 0 to 65535.
UnsignedTinyInt	An 8-bit unsigned integer. The <i>UnsignedTinyInt</i> value type represents unsigned integers with values that range from 0 to 255
WChar	A null-terminated stream of Unicode characters. A <i>WChar</i> is a sequential collection of Unicode characters that is used to represent text.

AMO Validations on Data Types

The following table lists the extra validations that Analysis Management Objects (AMO) does for certain bindings:

[\[+\] Expand table](#)

Object	Binding	Allowed Data Types
DimensionAttribute	KeyColumns	All but Binary
	NameColumn	Only WChar
	SkippedLevelsColumn	Only integer types: BigInt, Integer, SmallInt, TinyInt, UnsignedBigInt, UnsignedInt, UnsignedSmallInt, UnsignedTinyInt
	CustomRollupColumn	Only WChar
	CustomRollupPropertiesColumn	Only WChar
	UnaryOperatorColumn	Only WChar
	ValueColumn	All
AttributeTranslation	CaptionColumn	Only WChar

Object	Binding	Allowed Data Types
ScalarMiningStructureColumn	KeyColumns	All but Binary
	NameColumn	Only WChar
TableMiningStructureColumn	ForeignKeyColumns	All but Binary
MeasureGroupAttribute	KeyColumns	All but Binary
Distinct Count Measure	Source	BigInt, Currency, Double, Integer, Single, SmallInt, TinyInt, UnsignedBigInt, UnsignedInt, UnsignedSmallInt, UnsignedTinyInt

Local Cubes (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to: ✓ SQL Server Analysis Services ✖ Azure Analysis Services ✖ Fabric/Power BI Premium

To create, update or delete local cubes, you must write and execute either an ASSL script or an AMO program.

Local cubes and local mining models allow analysis on a client workstation while it is disconnected from the network. For example, a client application might call the OLE DB for OLAP 9.0 Provider (MSOLAP.3), which loads the local cube engine to create and query local cubes, as shown in the following illustration:

ADMOD.NET and Analysis Management Objects (AMO) also load the local cube engine when interacting with local cubes. Only a single process can access a local cube file, because the local cube engine exclusively locks a local cube file when it establishes a connection to the local cube. With a process, up to five simultaneous connections are permitted.

A .cub file may contain more than one cube or data mining model. Queries to the local cubes and data mining models are handled by the local cube engine and do not require a connection to an SQL Server Analysis Services instance.

Note

The use of SQL Server Management Studio and SQL Server Data Tools to manage local cubes is not supported.

Local Cubes

A local cube can be created and populated from either an existing cube in an SQL Server Analysis Services instance or from a relational data source.

 Expand table

Source for data for local cube	Creation method
Server-based cube	You can use either the CREATE GLOBAL CUBE statement or an SQL Server Analysis Services Scripting Language (ASSL) script to create and populate a cube from a server-based cube. For more information, see CREATE GLOBAL CUBE Statement (MDX) or Analysis Services Scripting Language (ASSL for XMLA) .
Relational data source	You use an ASSL script to create and populate a cube from an OLE DB relational database. To create a local cube using ASSL, you simply connect to a local cube file (*.cub) and execute the ASSL script in the same manner as executing an ASSL script against an SQL Server Analysis Services instance to create a server cube. For more information, see Analysis Services Scripting Language (ASSL for XMLA) .

Use the REFRESH CUBE statement to rebuild a local cube and update its data. For more information, see [REFRESH CUBE Statement \(MDX\)](#).

Local Cubes Created from Server-based Cubes

When creating local cubes created from server-based cubes, the following considerations apply:

- Distinct count measures are not supported.
- When you add a measure, you must also include at least one dimension that is related to the measure being added. For more information about dimension relationships to measure groups, see [Dimension Relationships](#).
- When you add a parent-child hierarchy, levels and filters on a parent-child hierarchy are ignored and the entire parent-child hierarchy is included.
- Member properties are not created.
- When you include a semi-additive measure, no slices are permitted on either the Account or the Time dimension.
- Reference dimensions are always materialized.

- When you include a many-to-many dimension, the following rules apply:
 - You cannot slice the many-to-many dimension.
 - You must add a measure from the intermediary measure group.
 - You cannot slice any of the dimensions common to the two measure groups involved in the many-to-many relationship.
- Only those calculated members, named sets, and assignments that rely upon measures and dimensions added to the local cube will appear in the local cube. Invalid calculated members, named sets, and assignments will be automatically excluded.

Security

In order for a user to create a local cube from a server cube, the user must be granted **Drillthrough and Local Cube** permissions on the server cube. For more information, see [Grant cube or model permissions \(Analysis Services\)](#).

Local cubes are not secured using roles like server cubes. Anyone with file-level access to a local cube file can query cubes in it. You can use the **Encryption Password** connection property on a local cube file to set a password on the local cube file. Setting a password on a local cube file requires all future connections to the local cube file to use this password in order to query the file.

Maximum capacity specifications (Analysis Services)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The following tables specify the maximum sizes and numbers of various objects defined in SQL Server Analysis Services components under different server deployment modes.

This topic contains the following sections:

[Multidimensional and Data Mining \(DeploymentMode=0\)](#)

[SharePoint \(DeploymentMode=1\)](#)

[Tabular \(DeploymentMode=2\)](#)

Multidimensional and Data Mining (DeploymentMode=0)

MOLAP storage mode, which stores both data and metadata, has additional physical limits on file sizes. String store files are a maximum size of 4 GB by default. If you require larger files for string stores, you can specify a different string storage architecture. For more information, see [Configure String Storage for Dimensions and Partitions](#).

 [Expand table](#)

Object	Maximum sizes/numbers
Databases in an instance	$2^{31}-1 = 2,147,483,647$
Dimensions in a database	$2^{31}-1 = 2,147,483,647$
Attributes in a dimension	$2^{31}-1 = 2,147,483,647$
Members in a dimension attribute	$2^{31}-1 = 2,147,483,647$
User-defined hierarchies in a dimension	$2^{31}-1 = 2,147,483,647$
Levels in a user-defined hierarchy	$2^{31}-1 = 2,147,483,647$
Cubes in a database	$2^{31}-1 = 2,147,483,647$

Object	Maximum sizes/numbers
Measure groups in a cube	$2^{31}-1 = 2,147,483,647$
Measures in a measure group	$2^{31}-1 = 2,147,483,647$
Calculations in a cube	$2^{31}-1 = 2,147,483,647$
KPIs in a cube	$2^{31}-1 = 2,147,483,647$
Actions in a cube	$2^{31}-1 = 2,147,483,647$
Partitions in a cube	$2^{31}-1 = 2,147,483,647$
Translations in a cube	$2^{31}-1 = 2,147,483,647$
Aggregations in a partition	$2^{31}-1 = 2,147,483,647$
Cells returned by a query	$2^{31}-1 = 2,147,483,647$
Record size of the source query	64K
Length of object names	100 characters
Maximum number of distinct states in a data mining model attribute column	$2^{31}-1 = 2,147,483,647$
Maximum number of attributes considered (feature selection)	$2^{31}-1 = 2,147,483,647$

For more information about object naming guidelines, see [ASSL Objects and Object Characteristics](#).

For more information about data source limitations for online analytical processing (OLAP) and data mining, see [Supported Data Sources \(SSAS - Multidimensional\)](#), [Supported Data Sources \(SSAS - Multidimensional\)](#), and [ASSL Objects and Object Characteristics](#).

Object Naming Rules (Analysis Services)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

This topic describes object naming conventions, as well as the reserved words and characters that cannot be used in any object name, in code or script in SQL Server Analysis Services.

Naming Conventions

Every object has a **Name** and **ID** property that must be unique within the scope of the parent collection. For example, two dimensions can have same name as long as each one resides in a different database.

Although you can specify it manually, the **ID** is typically auto-generated when the object is created. You should never change the **ID** once you have begun building a model. All object references throughout a model are based on the **ID**. Thus, changing an **ID** can easily result in model corruption.

DataSource and **DataSourceView** objects have notable exceptions to naming conventions. **DataSource** ID can be set to a single dot (.), which is not unique, as a reference to the current database. A second exception is **DataSourceView**, which adheres to the naming conventions defined for **DataSet** objects in the .NET Framework, where the **Name** is used as the identifier.

The following rules apply to **Name** and **ID** properties.

- Names are case insensitive. You cannot have a cube named "sales" and another named "Sales" in the same database.
- No leading or trailing spaces allowed in an object name, although you can embed spaces within a name. Leading and trailing spaces are implicitly trimmed. This applies to both the **Name** and **ID** of an object.
- The maximum number of characters is 100.
- There is no special requirement for the first character of an identifier. The first character may be any valid character.

Reserved Words and Characters

Reserved words are in English, and apply to object names, not Captions. If you inadvertently use a reserved word in an object name, a validation error will occur. For multidimensional and data mining models, the reserved words described below cannot be used in any object name, at any time.

For tabular models, where the database compatibility is set to 1103, validation rules have been relaxed for certain objects, out of compliance for the extended character requirements and naming conventions of certain client applications. Databases that meet these criteria are subject to less stringent validation rules. In this case, it's possible for an object name to include a restricted character and still pass validation.

Reserved Words

- AUX
- CLOCK\$
- COM1 through COM9 (COM1, COM2, COM3, and so on)
- CON
- LPT1 through LPT9 (LPT1, LPT2, LPT3, and so on)
- NUL
- PRN
- NULL is not allowed as a character in any string within the XML

Reserved Characters

The following table lists invalid characters for specific objects.

 Expand table

Object	Invalid characters
Server	Follow Windows server naming conventions when naming a server object. See Naming Conventions (Windows) for details.
DataSource	: /* ?"()[]{}<>
Level or Attribute	. , ; ` : /* ?" & % \$! + = [] {} < >
Dimension or	. , ; ` : /* ?" & % \$! + = ()[]{} <,>

Object	Invalid characters
Hierarchy	
All other objects	. , ; ' ` : / \ * ? " & % \$! + = () [] { } < >

Exceptions: When Reserved Characters are Allowed

As noted, databases of a specific modality and compatibility level can have object names that include reserved characters. Dimension attribute, hierarchy, level, measure and KPI object names can include reserved characters, for tabular databases (1103 or higher) that allow the use of extended characters:

 Expand table

Server mode and database compatibility level	Reserved characters allowed?
MOLAP (all versions)	No
Tabular - 1050	No
Tabular - 1100	No
Tabular - 1130 and higher	Yes

Databases can have a ModelType of default. Default is equivalent to multidimensional, and thus does not support the use of reserved characters in column names.

OLAP Engine Server Components

Article • 12/09/2022

Applies to: ✓ SQL Server Analysis Services ✖ Azure Analysis Services ✖
Fabric/Power BI Premium

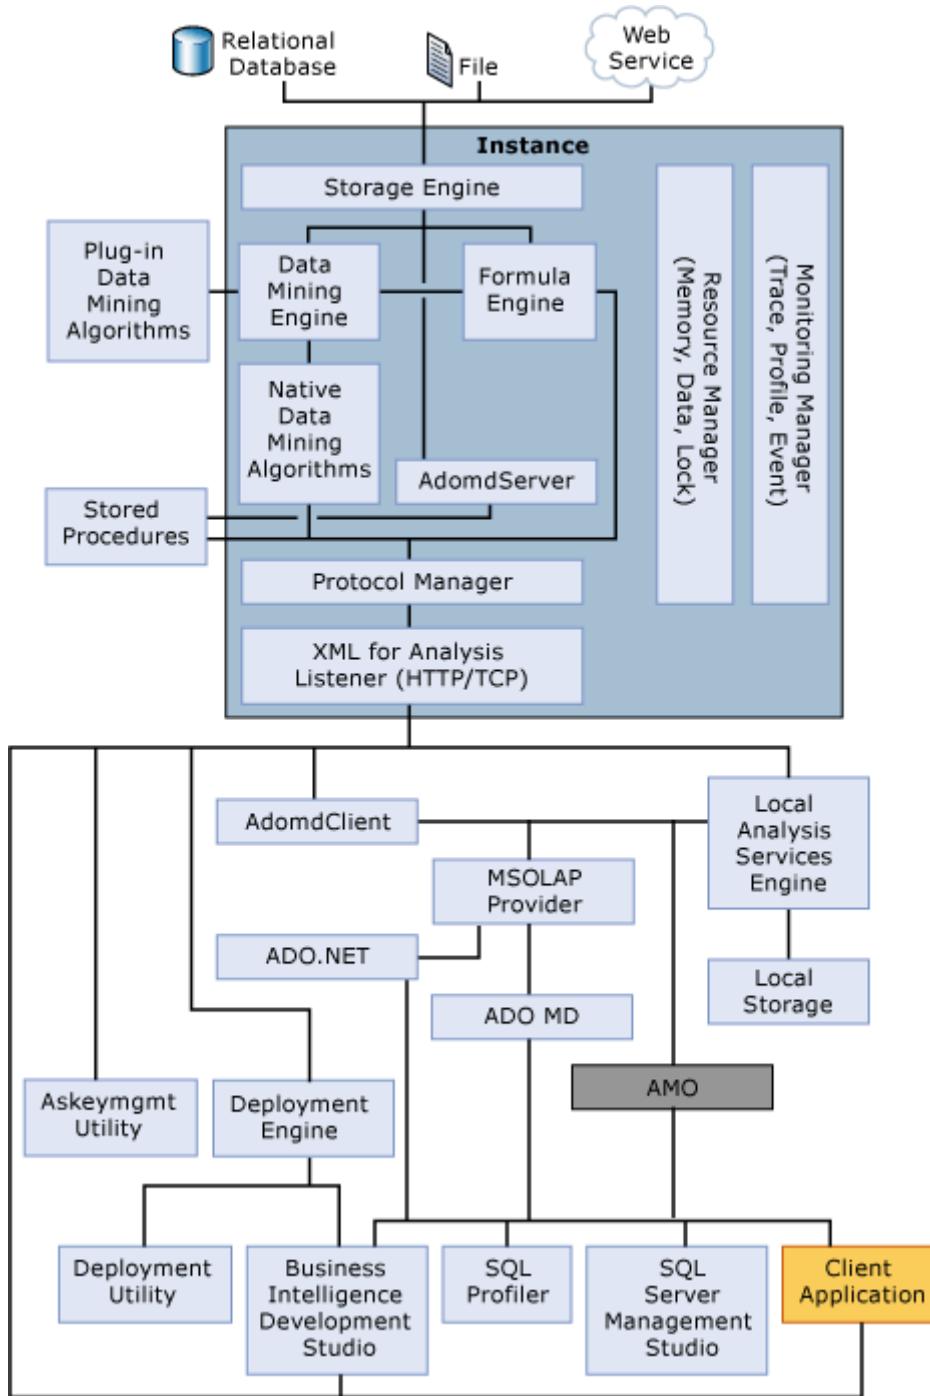

The server component of Microsoft SQL Server SQL Server Analysis Services is the `msmdsrv.exe` application, which runs as a Windows service. This application consists of security components, an XML for Analysis (XMLA) listener component, a query processor component and numerous other internal components that perform the following functions:

- Parsing statements received from clients
- Managing metadata
- Handling transactions
- Processing calculations
- Storing dimension and cell data
- Creating aggregations
- Scheduling queries
- Caching objects
- Managing server resources

Architectural Diagram

An SQL Server Analysis Services instance runs as a stand-alone service and communication with the service occurs through XML for Analysis (XMLA), by using either HTTP or TCP. AMO is a layer between the user application and the SQL Server Analysis Services instance. This layer provides access to SQL Server Analysis Services administrative objects. AMO is a class library that takes commands from a client application and converts those commands into XMLA messages for the SQL Server Analysis Services instance. AMO presents SQL Server Analysis Services instance objects as classes to the end user application, with method members that run commands and property members that hold the data for the SQL Server Analysis Services objects.

The following illustration shows the SQL Server Analysis Services components architecture, including all major elements running within the SQL Server Analysis Services instance and all user components that interact with the instance. The illustration also shows that the only way to access the instance is by using the XML for Analysis (XMLA) Listener, either by using HTTP or TCP.

XMLA Listener

The XMLA listener component handles all XMLA communications between SQL Server Analysis Services and its clients. The SQL Server Analysis Services **Port** configuration setting in the msmdsrv.ini file can be used to specify a port on which an SQL Server Analysis Services instance listens. A value of 0 in this file indicates that SQL Server

Analysis Services listen on the default port. Unless otherwise specified, SQL Server Analysis Services uses the following default TCP ports:

[] [Expand table](#)

Port	Description
2383	Default instance of SQL Server SQL Server Analysis Services.
2382	Redirector for other instances of SQL Server SQL Server Analysis Services.
Dynamically assigned at server startup	Named instance of SQL Server SQL Server Analysis Services.

See [Configure the Windows Firewall to Allow Analysis Services Access](#) for more details.

Extending OLAP functionality

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

As a programmer, you can extend Analysis Services by writing assemblies, personalized extensions, and stored procedures that provide functionality you want to use and repurpose in multiple database applications. Assemblies are used to extend multidimensional models functionality by adding new procedures and functions to the MDX language or by means of the personalization addin.

Stored procedures can be used to call external routines, simplifying Analysis Services database development and implementation by allowing common code to be developed once and stored in a single location. Stored procedures can be used to add business functionality to your applications that is not provided by the native functionality of MDX.

Personalizations are custom objects that you add to a cube to provide a behavior that varies by user. Personalizations are not permanent objects in the cube, but are objects that the client application applies dynamically during the user's session. Examples include changing the currency of a monetary value depending on the person accessing the data, providing individualized KPIs, or a targeted suggestion list for regular customers who purchase online.

Extending OLAP through personalizations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Analysis Services provides many intrinsic functions for use with the Multidimensional Expressions (MDX) and Data Mining Extensions (DMX) languages. These functions are designed to accomplish everything from standard statistical calculations to traversing members in a hierarchy. However, as with any other complex and robust product, there is always the need to extend the functionality of such a product further.

Therefore, Analysis Services provides you with the ability to add assemblies and personalized extensions to an instance of the service, in order to complete your business needs whenever the standard functionality is not enough.

Assemblies

Assemblies enable you to extend the business functionality of MDX and DMX. You build the functionality that you want into a library, such as a dynamic link library (DLL), then add the library as an assembly to an instance of Analysis Services or to an Analysis Services database. The public methods in the library are then exposed as user-defined functions to MDX and DMX expressions, procedures, calculations, actions, and client applications.

Personalized Extensions

SQL Server Analysis Services personalization extensions are the foundation of the idea of implementing a plug-in architecture. Analysis Services personalization extensions are a simple and elegant modification to the existing managed assembly architecture and are exposed throughout the Analysis Services Microsoft.AnalysisServices.AdomdServer object model, Multidimensional Expressions (MDX) syntax, and schema rowsets.

Analysis Services Personalization Extensions

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

SQL Server SQL Server Analysis Services personalization extensions are the foundation of the idea of implementing a plug-in architecture. In a plug-in architecture, you can develop new cube objects and functionality dynamically and share them easily with other developers. As such, SQL Server Analysis Services personalization extensions provide the functionality that makes it possible to achieve the following:

- **Dynamic design and deployment** Immediately after you design and deploy SQL Server Analysis Services personalization extensions, users have access to the objects and functionality at the start of the next user session.
- **Interface independence** Regardless of the interface that you use to create the SQL Server Analysis Services personalization extensions, users can use any interface to access the objects and functionality.
- **Session context** SQL Server Analysis Services personalization extensions are not permanent objects in the existing infrastructure and do not require the cube to be reprocessed. They become exposed and created for the user at the time that the user connects to the database, and remain available for the length of that user session.
- **Rapid distribution** Share SQL Server Analysis Services personalization extensions with other software developers without having to go into detailed specifications about where or how to find this extended functionality.

SQL Server Analysis Services personalization extensions have many uses. For example, your company has sales that involve different currencies. You create a calculated member that returns the consolidated sales in the local currency of the person who is accessing the cube. You create this member as a personalization extension. You then share this calculated member to a group of users. Once shared, those users have immediate access to the calculated member as soon as they connect to the server. They have access even if they are not using the same interface as the one that was used to create the calculated member.

SQL Server Analysis Services personalization extensions are a simple and elegant modification to the existing managed assembly architecture and are exposed throughout the SQL Server Analysis Services Microsoft.AnalysisServices.AdomdServer object model, Multidimensional Expressions (MDX) syntax, and schema rowsets.

Logical Architecture

The architecture for SQL Server Analysis Services personalization extensions is based on the managed assembly architecture and the following four basic elements:

The [PlugInAttribute] custom attribute

When starting the service, SQL Server Analysis Services loads the required assemblies and determines which classes have the

Microsoft.AnalysisServices.AdomdServer.PlugInAttribute custom attribute.

ⓘ Note

The .NET Framework defines custom attributes as a way to describe your code and affect run-time behavior. For more information, see the topic, "[Attributes Overview](#)" in the .NET Framework Developer's Guide on MSDN.

For all classes with the Microsoft.AnalysisServices.AdomdServer.PlugInAttribute custom attribute, SQL Server Analysis Services invokes their default constructors. Invoking all the constructors at startup provides a common location from which to build new objects and that is independent of any user activity.

In addition to building a small cache of information about authoring and managing personalization extensions, the class constructor typically subscribes to the Microsoft.AnalysisServices.AdomdServer.Server.SessionOpened and Microsoft.AnalysisServices.AdomdServer.Server.SessionClosing events. Failing to subscribe to these events may cause the class to be inappropriately marked for cleanup by the common language runtime (CLR) garbage collector.

Session context

For those objects that are based on personalization extensions, SQL Server Analysis Services creates an execution environment during the client session and dynamically builds most of those objects in this environment. Like any other CLR assembly, this execution environment also has access to other functions and stored procedures. When the user session ends, SQL Server Analysis Services removes the dynamically created objects and closes the execution environment.

Events

Object creation is triggered by the session events **On-Cube-Opened****CubeOpened** and **On-Cube-Closing****CubeClosing**.

Communication between the client and the server occurs through specific events. These events make the client aware of the situations that lead to the client's objects being built. The client's environment is dynamically created using two sets of events: session events and cube events.

Session events are associated with the server object. When a client logs on to a server, SQL Server Analysis Services creates a session and triggers the Microsoft.AnalysisServices.AdomdServer.Server.SessionOpened event. When a client ends the session on the server, SQL Server Analysis Services triggers the Microsoft.AnalysisServices.AdomdServer.Server.SessionClosing event.

Cube events are associated with the connection object. Connecting to a cube triggers the Microsoft.AnalysisServices.AdomdServer.AdomdConnection.CubeOpened event. Closing the connection to a cube, by either closing the cube or by changing to a different cube, triggers a Microsoft.AnalysisServices.AdomdServer.AdomdConnection.CubeClosing event.

Traceability and error handling

All activity is traceable by using SQL Server Profiler. Unhandled errors are reported to the Windows event log.

All object authoring and management is independent of this architecture and is the sole responsibility of the developers of the objects.

Infrastructure Foundations

SQL Server Analysis Services personalization extensions are based on existing components. The following is a summary of enhancements and improvements that provide the personalization extensions functionality.

Assemblies

The custom attribute, Microsoft.AnalysisServices.AdomdServer.PluginAttribute, can be added to your custom assemblies to identify SQL Server Analysis Services personalization extensions classes.

Changes to the AdomdServer Object Model

The following objects in the Microsoft.AnalysisServices.AdomdServer object model have been enhanced or added to the model.

New AdomdConnection Class

The Microsoft.AnalysisServices.AdomdServer.AdomdConnection class is new and exposes several personalization extensions through both properties and events.

Properties

- Microsoft.AnalysisServices.AdomdServer.AdomdConnection.SessionID, a read-only string value representing the session Id of the current connection.
- Microsoft.AnalysisServices.AdomdServer.AdomdConnection.ClientCulture, a read-only reference to the client culture associated with current session.
- Microsoft.AnalysisServices.AdomdServer.AdomdConnection.User, a read-only reference to the identity interface representing the current user.

Events

- Microsoft.AnalysisServices.AdomdServer.AdomdConnection.CubeOpened
- Microsoft.AnalysisServices.AdomdServer.AdomdConnection.CubeClosing

New Properties in the Context class

The Microsoft.AnalysisServices.AdomdServer.Context class has two new properties:

- Microsoft.AnalysisServices.AdomdServer.Context.Server, a read-only reference to the new server object.
- Microsoft.AnalysisServices.AdomdServer.Context.CurrentConnection, a read-only reference to the new Microsoft.AnalysisServices.AdomdServer.AdomdConnection object.

New Server class

The Microsoft.AnalysisServices.AdomdServer.Server both class properties and events.

Properties

- Microsoft.AnalysisServices.AdomdServer.Server.Name, a read-only string value representing the server name.

- Microsoft.AnalysisServices.AdomdServer.Server.Culture, A read-only reference to the global culture associated with the server.

Events

- Microsoft.AnalysisServices.AdomdServer.Server.SessionOpened
- Microsoft.AnalysisServices.AdomdServer.Server.SessionClosing

AdomdCommand class

The Microsoft.AnalysisServices.AdomdServer.AdomdCommand class now supports of the following MDX commands:

- [CREATE MEMBER Statement \(MDX\)](#)
- [UPDATE MEMBER Statement \(MDX\)](#)
- [DROP MEMBER Statement \(MDX\)](#)
- [CREATE SET Statement \(MDX\)](#)
- [DROP SET Statement \(MDX\)](#)
- [CREATE KPI Statement \(MDX\)](#)
- [DROP KPI Statement \(MDX\)](#)

MDX extensions and enhancements

The CREATE MEMBER command is enhanced with the **caption** property, the **display_folder** property, and the **associated_measure_group** property.

The UPDATE MEMBER command is added to avoid member re-creation when an update is needed with the consequent loss of precedence in solving calculations. Updates cannot change the scope of the calculated member, move the calculated member to a different parent, or define a different **solveorder**.

The CREATE SET command is enhanced with the **caption** property, the **display_folder** property, and the new **STATIC | DYNAMIC** keyword. *Static* means that set is evaluated only at creation time. *Dynamic* means that the set is evaluated every time that the set is used in a query. The default value is **STATIC** if a keyword is omitted.

CREATE KPI and DROP KPI commands are added to the MDX syntax. KPIs can be created dynamically from any MDX script.

Schema Rowsets extensions

On MDSHEMA_MEMBERS *scope* column is added. Scope values are as follows:
MDMEMBER_SCOPE_GLOBAL=1, MDMEMBER_SCOPE_SESSION=2.

On MDSHEMA_SETS *set_evaluation_context* column is added. Set evaluation context values are as follows: MDSET_RESOLUTION_STATIC = 1, MDSET_RESOLUTION_DYNAMIC = 2.

On MDSHEMA_KPIS scope column is added. Scope values are as follows:
MDKPI_SCOPE_GLOBAL=1, MDKPI_SCOPE_SESSION=2.

Accessing Query Context in Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The execution context of a stored procedure is available within the code of the stored procedure as the **Context** object of the ADOMD.NET server object model. This is a read-only context and cannot be modified by the stored procedure. The following properties are available on this object.

 Expand table

Property	Type	Description
CurrentCube	Cube	The cube for the current query context.
CurrentDatabaseName	String	The identifier of the current database.
CurrentConnection	Connection	A reference to the connection object in the current context.
Pass	Integer	The pass number for the current context.

The **Context** object exists when the Multidimensional Expressions (MDX) object model is used in a stored procedure. It is not available when the MDX object model is used on a client. The **Context** object is not explicitly passed to or returned by the stored procedure. It is available during the execution of the stored procedure.

Calling Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Stored procedures can be called on the server or from client application. In either case, stored procedures always run on the server, either the context of the server or of a database. There are no special permissions required to execute a stored procedure. Once a stored procedure is added by an assembly to the server or database context, any user can execute the stored procedure as long as the role for the user permits the actions performed by the stored procedure.

Calling a stored procedure in MDX is done in the same manner as calling an intrinsic MDX function. For a stored procedure that takes no parameters, the name of the procedure and an empty pair of parentheses are used, as shown here:

```
My.StoredProcedure()
```

If the stored procedure takes one or more parameters, then the parameters are supplied, in order, separated by commas. The following example demonstrates a sample stored procedure with three parameters:

```
My.StoredProcedure("Parameter1", 2, 800)
```

Calling Stored Procedures in MDX Queries

In all MDX queries, the stored procedure must return the syntactically correct type required by an MDX expression. If a stored procedure does not return the correct type, an MDX error occurs. The following examples demonstrate stored procedures that return a set, a member, and the result of a mathematical operation.

Returning a Set

The following examples implement a stored procedure, called MySproc, that returns a set. In the first example, MySproc returns the set directly in the SELECT expression. In the

second two examples, MySproc returns the set as an argument for the Crossjoin and DrilldownLevel functions.

```
SELECT MySetProcedure(a,b,c) ON 0 FROM Sales  
SELECT Crossjoin(MySetProcedure(a,b,c)) ON 0 FROM Sales  
SELECT DrilldownLevel(MySetProcedure(a,b,c)) ON 0 FROM Sales
```

Returning a Member

The following example shows a function MySproc function that returns a member:

```
SELECT Descendants(MySproc(a,b,c),3) ON 0 FROM Sales
```

Returning the Result of a Math Operation

```
SELECT Country.Members on 0, MySproc(Measures.Sales) ON 1 FROM Sales
```

Calling Stored Procedures with the Call Statement

Stored procedures can be called outside of the context of an MDX query using the MDX **Call** statement.

You can use this method to either instantiate the side effects of a stored query or for the application to get the results of a stored query. A common use of the **Call** statement would be to use Analysis Management Objects (AMO) to perform administrative functions that do not have a return result. For example, the following command calls a stored procedure:

```
Call MyStoredProcedure(a,b,c)
```

The only supported type returned from stored procedure in a **Call** statement is a rowset. The serialization for a rowset is defined by XML for Analysis. If a stored procedure in a

Call statement returns any other type, it is ignored and not returned in XML to the calling application. For more information about XML for Analysis rowsets, see, XML for Analysis Schema Rowsets.

If a stored procedure returns a .NET rowset, SQL Server Analysis Services converts the result on the server to an XML for Analysis rowset. The XML for Analysis rowset is always returned by a stored procedure in the **Call** function. If a dataset contains features that cannot be expressed in the XML for Analysis rowset, a failure results.

Procedures that return void values (for example, subroutines in Visual Basic) can also be employed with the **CALL** keyword. If, for example, you wanted to use the function `MyVoidFunction()` in an MDX statement, the following syntax would be employed:

```
CALL(MyVoidFunction)
```

Creating Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

All stored procedures must be associated with a common language runtime (CLR) or Component Object Model (COM) class in order to be used. The class must be installed on the server - usually in the form of a Microsoft ActiveX® dynamic link library (DLL) - and registered as an assembly on the server or in an SQL Server Analysis Services database.

Stored procedures are registered on a server or on a database. Server stored procedures can be called from any query context. Database stored procedures can only be accessed if the database context is the database under which the stored procedure is defined. If functions in one assembly call functions in a different assembly, you must register both assemblies in the same context (server or database). For a server or a deployed Microsoft SQL Server SQL Server Analysis Services database on a server, you can use SQL Server Management Studio to register an assembly. For an SQL Server Analysis Services project, you can use SQL Server Analysis Services Designer to register an assembly in the project.

Important

COM assemblies might pose a security risk. Due to this risk and other considerations, COM assemblies were deprecated in SQL Server 2008 Analysis Services (SSAS). COM assemblies might not be supported in future releases.

Registering a Server Assembly

In Object Explorer in SQL Server Management Studio, server assemblies are listed in the Assemblies folder under an instance of SQL Server Analysis Services. Server assemblies can contain both .NET (CLR) assemblies and COM libraries.

To create a server assembly

1. Expand the instance of SQL Server Analysis Services in Object Explorer, right-click the **Assemblies** folder, and then click **New Assembly**. This displays the **Register Server Assembly** dialog box.

2. For **Type** specify the type of assembly:

- For a managed code (CLR) DLL, specify .NET Assembly.
- For a native code (COM) DLL, specify COM DLL.

3. For **File name**, specify the DLL containing the stored procedures.

4. For **Assembly name**, specify a name for the assembly.

5. If this is a debug build of the library that you are going to use to debug stored procedures, select the **Include debug information** check box. For more information about debugging stored procedures, see [Debugging Stored Procedures](#).

6. You can click **OK** to register the assembly immediately, or on the dialog box toolbar, you can click a command on the **Script** menu to script the registration action to a query window, a file, or the Clipboard.

After you register a server assembly, you can configure it by right-clicking the assembly in Object Explorer and then clicking **Properties**.

Registering a Database Assembly on the Server

In Object Explorer in SQL Server Management Studio, database assemblies are listed in the **Assemblies** folder under an SQL Server Analysis Services database. Database assemblies can contain both .NET (CLR) assemblies and COM libraries.

To create a database assembly on a server

1. Expand the instance the SQL Server Analysis Services database in Object Explorer, right-click the **Assemblies** folder, and then click **New Assembly**. This displays the **Register Database Assembly** dialog box.

2. For **Type** specify the type of assembly:

- For a managed code (CLR) DLL, specify .NET Assembly.
- For a native code (COM) DLL, specify COM DLL.

3. For **File name**, specify the DLL containing the stored procedures.

4. For **Assembly name**, specify a name for the assembly.

5. If this is a debug build of the library that you are going to use to debug stored procedures, select the **Include debug information** check box. For more information about debugging stored procedures, see [Debugging Stored Procedures](#).
6. You can click **OK** to register the assembly immediately, or on the dialog box toolbar, you can click a command on the **Script** menu to script the registration action to a query window, a file, or the Clipboard.

After you register a database assembly, you can configure it by right-clicking the assembly in Object Explorer and then clicking **Properties**.

Registering a Database Assembly in a Project

In Solution Explorer in SQL Server Data Tools, database assemblies are listed in the **Assemblies** folder under an SQL Server Analysis Services project. Database assemblies can contain both .NET (CLR) assemblies and COM libraries.

To create a database assembly in an Analysis Service project

1. Expand the instance the SQL Server Analysis Services database in Object Explorer, right-click the **Assemblies** folder, and then click **New Assembly Reference**. This displays the **Add Reference** dialog box. The **.NET** tab of the **Add Reference** dialog box lists existing .NET (CLR) assemblies, while the **Projects** tab lists projects.
2. You can click an existing component or project and then click **Add** to add it to the SQL Server Analysis Services project. To add a reference to a COM DLL, click the **Browse** tab to find the file. The **Selected projects and components** list shows the name, type, version, and location for each component that you are adding to the project.
3. When you are finished selecting components to add, click **OK** to add them to the SQL Server Analysis Services project.

Script Format For an Assembly

Registering a .NET assembly is fairly simple. A .NET assembly is added to a database in binary format using the following format:

```
<Create>
  <ObjectDefinition>
    <Assembly>
      <Files>
        <File>
          <Name>filename</Name>
          <Type>filetype</Type>
          <Data>
            <Block>binarydatablock</Block>
            <Block>binarydatablock</Block>
            ...
          </Data>
        </File>
      </Files>
      <PermissionSet>PermissionSet</PermissionSet>
    </Assembly>
  <ObjectDefinition>
</Create>
```

Debugging Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

SQL Server Analysis Services stored procedures are actually CLR or COM libraries (normally DLLs) that are written in C# (or any other CLR or COM language). Therefore, debugging a stored procedure is much like debugging any other application in the Visual Studio debugging environment. You debug stored procedures in the Visual Studio development environment using the integrated debugging functions. These allow you to stop at procedure locations, inspect memory and register values, change variables, observe message traffic and get a close look at how your code works.

To debug a stored procedure

1. Open the project used to create the DLL in Visual Studio.
2. Create breakpoints in the method or function corresponding to the procedure you want to debug.
3. Use Visual Studio to create a debug build of a stored procedure DLL.
4. Deploy the DLL to the server. For more information about deploying the DLL to the server, see [Creating Stored Procedures](#).
5. You need an application that calls the stored procedure that you want to test. If you do not have one ready, you can use the MDX Query Editor in SQL Server Management Studio to create an MDX query that calls the stored procedure that you want to test.
6. In Visual Studio, attach to the SQL Server Analysis Services process (Msmdsrv.exe).
 - a. From the **Debug** menu, choose **Attach to Process**.
 - b. In the **Attach to Process** dialog box, select **Show processes from all users**.
 - c. In the **Available Processes** list, in the **Process** column, click **Msmdsrv.exe**. If there is more than one instance of SQL Server Analysis Services running on the server, you need to identify the process by the ID of the instance you want to use.

d. In the **Attach to** text box, make sure that the appropriate program type is selected. For a CLR DLL, click **Select**, then click **Debug these code types**, then click **Managed**, then click **OK**. For a COM DLL, click **Select**, then click **Debug these code types**, then click **Native**, then click **OK**.

e. Click **Attach**.

7. In SQL Server Analysis Services, invoke the program or MDX script that calls the stored procedure. The debugger breaks when it reaches a line containing a breakpoint. You can evaluate variables in the watch window, view locals, and step through the code.

If you have problems debugging a library, make sure that the corresponding program database (PDB) file was copied to the deployment location on the server. If this file was not copied during registration or deployment, you must copy it manually to the same location as the DLL. For native code (COM DLL), the PDB file resides in the \debug subdirectory. For managed code (CLR DLL), it resides in the \WINDEBUG subdirectory.

Defining Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

You can use stored procedures to call external routines from Microsoft SQL Server SQL Server Analysis Services. You can write an external routines called by a stored procedure in any common language runtime (CLR) language, such as C, C++, C#, Visual Basic, or Visual Basic .NET. A stored procedure can be created once and called from many contexts, such as other stored procedures, calculated measures, or client applications. Stored procedures simplify SQL Server Analysis Services database development and implementation by allowing common code to be developed once and stored in a single location. Stored procedures can be used to add business functionality to your applications that is not provided by the native functionality of MDX.

This section provides the information necessary to understand, design, and implement stored procedures.

Designing Stored Procedures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Both the administrative object model Analysis Management Objects (AMO) and the client oriented object model Microsoft ActiveX® Data Objects (Multidimensional) (ADO MD) are available in stored procedures.

Stored procedures must be in scope (either the server or the database) to be visible at the Multidimensional Expressions (MDX) level to be called. However, once a stored procedure is invoked, its scope is not limited to actions under its parent. A stored procedure may make changes or modifications anywhere on the server, subject only to the security limitations of the user process that invokes it or to the limitations of the transaction in which it is operating.

Server scope procedures are available in all contexts on the server. Database scope stored procedures are visible only in the database context of the database in which they are defined.

As with any MDX function, stored procedure must be resolved before an MDX session can continue; stored procedures lock MDX sessions while executing. Unless a specific reason exists to halt an MDX session pending user interaction, then user interactions (such as dialog boxes) are discouraged.

Dependent Assemblies

All dependent assemblies must be loaded into an instance of SQL Server Analysis Services to be found by the common language runtime (CLR). SQL Server Analysis Services stores the dependent assemblies in the same folder as the main assembly, so the CLR automatically resolves all function references to functions in those assemblies.

Multidimensional Model Data Access (Analysis Services - Multidimensional Data)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Use the information in this topic to learn how to access SQL Server Analysis Services multidimensional data using programmatic methods, script, or client applications that include built-in support for connecting to an SQL Server Analysis Services server on your network.

This topic contains the following sections:

[Client Applications](#)

[Query Languages](#)

[Programmatic Interfaces](#)

Client Applications

Although Analysis Services provides interfaces that let you build or integrate multidimensional databases programmatically, a more common approach is to use existing client applications from Microsoft and other software vendors that have built-in data access to Analysis Services data.

The following Microsoft applications support native connections to multidimensional data.

Excel

Analysis Services multidimensional data is often presented using pivot tables and pivot chart controls in an Excel workbook. PivotTables are suited to multidimensional data because the hierarchies, aggregations, and navigational constructs in the model pair well with the data summary features of a PivotTable. An Analysis Services OLE DB data provider is included in an Excel installation to make setting up data connections easier. For more information, see [Connect to or import data from SQL Server Analysis Services](#).

Reporting Services Reports

You can use Report Builder or Report Designer to create reports that consume Analysis Services databases that contain analytical data. Both Report Builder and Report Designer include an MDX query designer that you can use to type or design MDX statements that retrieve data from an available data source.

PerformancePoint Dashboards

PerformancePoint Dashboards are used to create scorecards in SharePoint that communicate business performance against predefined measures. PerformancePoint includes support for data connections to Analysis Services multidimensional data. For more information, [Create an Analysis Services data connection \(PerformancePoint Services\)](#).

SQL Server Data Tools

Model and report designers use SQL Server Data Tools to build solutions that include multidimensional models. Deploying the solution to an Analysis Services instance is what creates the database that you subsequently connect to from Excel, Reporting Services, and other business intelligence client applications.

SQL Server Data Tools is built on a Visual Studio shell and uses projects to organize and contain the model. For more information, see [Creating Multidimensional Models Using SQL Server Data Tools \(SSDT\)](#).

SQL Server Management Studio

For database administrators, SQL Server Management Studio is an integrated environment for managing your SQL Server instances, including instances of Analysis Services and multidimensional databases. For more information, see [SQL Server Management Studio](#).

Query Languages

MDX is an industry standard query and calculation language used to retrieve data from OLAP databases. In Analysis Services, MDX is the query language used to retrieve data, but also supports data definition and data manipulation. MDX editors are built into SQL Server Management Studio, Reporting Services, and SQL Server Data Tools. You can use

the MDX editors to create ad hoc queries or reusable script if the data operation is repeatable.

Some tools and applications, such as Excel, use MDX constructs internally to query an Analysis Services data source. You can also use MDX programmatically, by enclosing MDX statement in an XMLA Execute request.

The following links provide more information about MDX:

[Querying Multidimensional Data with MDX](#)

[Key Concepts in MDX \(Analysis Services\)](#)

[MDX Query Fundamentals \(Analysis Services\)](#)

[MDX Scripting Fundamentals \(Analysis Services\)](#)

Programmatic Interfaces

If you are building a custom application that uses multidimensional data, your approach for accessing the data will most likely fall into one of the following categories:

- **XMLA.** Use XMLA when you require compatibility with a wide variety of operating systems and protocols. XMLA offers the greatest flexibility, but often at the cost of improved performance and ease of programming.
- **Client libraries.** Use Analysis Services client libraries, such as ADOMD.NET, AMO, and OLE DB when you want to access data programmatically from client applications that run on a Microsoft Windows operating system. The client libraries wrap XMLA with an object model and optimizations that provide better performance.

ADOMD.NET and AMO client libraries are for applications written in managed code. Use OLE DB for Analysis Services if your application is written in native code.

The following table provides additional detail and links about the client libraries used for connecting Analysis Services to a custom application.

[+] [Expand table](#)

Interface	Description
Analysis Services	AMO is the primary object model for administering Analysis Services instances and multidimensional databases in code. For example, SQL Server Management Studio uses AMO to support server and database administration.

Interface	Description
Management Objects (AMO)	For more information, see Developing with Analysis Management Objects (AMO) .
ADOMD.NET	ADOMD.NET is the primary object model creating and accessing multidimensional data in custom applications. You can use ADOMD.NET in a managed client application to retrieve SQL Server Analysis Services information using common Microsoft .NET Framework data access interfaces. For more information, see Developing with ADOMD.NET and ADOMD.NET Client Programming .
Analysis Services OLE DB Provider (MSOLAP.dll)	You can use the native OLE DB provider to access SQL Server Analysis Services programmatically from a non-managed API. For more information, see Analysis Services OLE DB Provider (Analysis Services - Multidimensional Data) .
Schema Rowsets	Schema rowset tables are data structures that contain descriptive information about a multidimensional model that is deployed on the server, as well as information about current activity on the server. As a programmer, you can query schema rowset tables in client applications to examine metadata stored on, and retrieve support and monitoring information from, an SQL Server Analysis Services instance. You can use schema rowsets with these programmatic interfaces: OLE DB, OLE DB for Analysis Services, OLE DB for Data Mining, or XMLA.
The following list explains several approaches for using schema rowsets:	<ul style="list-style-type: none"> -Run DMV queries in SQL Server Management Studio or in custom reports to access schema rowsets using SQL syntax. For more information, see Use Dynamic Management Views (DMVs) to Monitor Analysis Services. -Write ADOMD.NET code that calls a schema rowset. -Run the XMLA Discover method directly against an SQL Server Analysis Services instance to retrieve schema rowset information. For more information, see Discover Method (XMLA).
XMLA	XMLA is the lowest level API available to an Analysis Services programmer, and is the common denominator that underlies all Analysis Services data access methodologies. XMLA is an industry standard, SOAP based XML protocol that supports universal data access to any standard multidimensional data source available over an HTTP connection. It uses SOAP to formulate requests and responses for multidimensional data. If your application runs on a non-Windows platform, you can use XMLA to access a multidimensional database that is running on a Windows server on your network. For more information, see Developing with XMLA in Analysis Services .
Analysis Services Scripting	ASSL is a descriptive term that applies to Analysis Services extensions of the XMLA protocol. Whereas the Execute and Discover methods are described by the XMLA protocol, ASSL adds the following capability:

Interface	Description
Language (ASSL)	<ul style="list-style-type: none">-XMLA script-XMLA object definitions-XMLA commands <p>ASSL extensions enable Analysis Services to use XMLA constructs beyond the basic provisions of the protocol, adding data definition, data manipulation, and data control support. For more information, see Developing with Analysis Services Scripting Language (ASSL).</p>

Querying Multidimensional Data with MDX

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Multidimensional Expressions (MDX) is the query language that you use to work with and retrieve multidimensional data in Microsoft SQL Server Analysis Services. MDX is based on the XML for Analysis (XMLA) specification, with specific extensions for SQL Server SQL Server Analysis Services. MDX utilizes expressions composed of identifiers, values, statements, functions, and operators that SQL Server Analysis Services can evaluate to retrieve an object (for example a set or a member), or a scalar value (for example, a string or a number).

MDX queries and expressions in SQL Server SQL Server Analysis Services are used to do the following:

- Return data to a client application from a SQL Server SQL Server Analysis Services cube.
- Format query results.
- Perform cube design tasks, including the definition of calculated members, named sets, scoped assignments, and key performance indicators (KPIs).
- Perform administrative tasks, including dimension and cell security.

MDX is superficially similar in many ways to the SQL syntax that is typically used with relational databases. However, MDX is not an extension of the SQL language and is different from SQL in many ways. In order to create MDX expressions used to design or secure cubes, or to create MDX queries to return and format multidimensional data, you need to understand basic concepts in MDX and dimensional modeling, MDX syntax elements, MDX operators, MDX statements, and MDX functions.

In This Section

 Expand table

Topic	Description
Key Concepts in MDX (Analysis Services)	You can use Multidimensional Expressions (MDX) to query multidimensional data or to create MDX expressions for use within a cube, but first you should understand SQL Server SQL Server Analysis Services dimension concepts and terminology.
MDX Query Fundamentals (Analysis Services)	Multidimensional Expressions (MDX) enables you to query multidimensional objects, such as cubes, and return multidimensional cellsets that contain the cube's data. This topic and its subtopics provide an overview of MDX queries.
MDX Scripting Fundamentals (Analysis Services)	<p>In SQL Server SQL Server Analysis Services, a Multidimensional Expressions (MDX) script is made up of one or more MDX expressions or statements that populate a cube with calculations.</p> <p>An MDX script defines the calculation process for a cube. An MDX script is also considered part of the cube itself. Therefore, changing an MDX script associated with a cube immediately changes the calculation process for the cube.</p> <p>To create MDX scripts, you can use Cube Designer in the SQL Server Data Tools.</p>

Key Concepts in MDX (Analysis Services)

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Before you can use Multidimensional Expressions (MDX) to query multidimensional data or create MDX expressions within a cube, it helps to understand multidimensional concepts and terms.

The best place to start is with a data summarization example you already know, and then see how MDX relates to it. Here's a PivotTable created in Excel, populated with data from an Analysis Services sample cube.

Reseller Sales Amount		Column Labels				
Row Labels		CY 2005	CY 2006	CY 2007	CY 2008	Grand Total
Europe		\$1,698,880.94	\$5,632,816.55	\$3,538,837.31	\$10,870,534.80	
North America		\$8,065,435.31	\$22,445,548.71	\$25,722,421.91	\$11,752,320.88	\$67,985,726.81
Canada		\$1,513,359.46	\$4,822,999.20	\$5,651,305.43	\$2,390,261.51	\$14,377,925.60

Northeast		\$568,545.52	\$2,443,901.73	\$2,863,937.85	\$1,056,456.93	\$6,932,842.01
Northwest		\$1,689,790.14	\$3,471,099.54	\$4,640,535.06	\$2,633,651.25	\$12,435,076.00
Southeast		\$1,448,921.51	\$2,815,903.10	\$2,429,279.90	\$1,173,311.72	\$7,867,416.23
Southwest		\$1,893,578.02	\$6,266,005.43	\$7,131,772.25	\$3,175,103.09	\$18,466,458.79
Pacific				\$847,430.96	\$746,904.41	\$1,594,335.38
Grand Total		\$8,065,435.31	\$24,144,429.65	\$32,202,669.43	\$16,038,062.60	\$80,450,596.98

Measures and Dimensions

An Analysis Services cube consists of measures, dimensions, and dimension attributes, all of which are evident in the PivotTable example.

Measures are numeric data values found in cells, aggregated as a sum, count, percentage, min, max, or average. Measure values are dynamic, calculated in real time, in response to user navigation and interaction with the PivotTable. In this example, the cells show Reseller Sales Amounts that increase or decrease based on whether you expand or collapse the axes. For any combination of Date (year, quarter, month, or date) and Sales Territory (Country group, Country, Region) you can get a Reseller Sales Amount, summed for that particular context. Other terms that are synonymous with measures are facts (in data warehouses) and calculated fields (in tabular and Excel data models).

Dimensions are on the column and row axes of a PivotTable, providing the meaning behind the measure. Dimensions are analogous to Tables in a relational data model. Common examples of a dimension include Time, Geography, Products, Customers, Employees, and so on. This example has two dimensions, Sales Territory on the rows, and Date across the top, but you could easily drag and drop other dimensions associated with Reseller Sales, such as Promotions or Products, to view sales performance along those dimensions. Your ability to explore data in interesting ways depends on the dimensions you create, and whether they are related to fact tables in your data source.

Dimension attributes are the named items within a dimension, similar to columns in a table. In this example, the Sales Territory dimension attributes consist of Country Group (Europe, North America, Pacific), Country (Canada, United States), and Region (Central, Northeast, Northwest, Southeast, Southwest).

Each attribute has a collection of data values, or members, associated with it. In our example, members of the Country Group attribute are Europe, North America, and Pacific. **Members** refers to the actual data values that belong to an attribute.

Note

One aspect of data modeling is to formalize the patterns and relationships that already exist within the data itself. When working with data that falls into a natural hierarchy, as is the case with countries/regions-regions-cities, you can formalize that relationship by creating an **attribute relationship**. An attribute relationship is a one-to-many relationship between attributes, for example a relationship between a state and a city - a state has many cities, but a city belongs to just one state. Creating attribute relationships in the model speeds up query performance, so it's a best practice to create them if the data supports it. You can create an attribute relationship in Dimension Designer in SQL Server Data Tools. See [Define Attribute Relationships](#).

Inside Excel, model metadata shows up in the PivotTable field list. Compare the PivotTable above to the field list below. Notice that the field list contains Sales Territory, Group, Country, Region (metadata), whereas the PivotTable contains just the members (data values). Knowing what the icons look like can help you easily relate the parts of a multidimensional model to a PivotTable in Excel.

Drag fields between areas below:

FILTERS	COLUMNS
	Date.Calendar
ROWS	VALUES
Sales Territory	Reseller Sales Amount

Attribute Hierarchies

Almost without having to think about it, you know that values in a PivotTable go up or down as you expand and collapse the levels along each axis, but what makes this so? The answer lies in attribute hierarchies.

Collapse all the levels and notice the grand totals for each Country Group and Calendar Year. This value is derived from something called the **(All) member** within a hierarchy. The (All) member is the calculated value of all members in an attribute hierarchy.

- The (All) member for all Country Groups and Dates combined is \$80,450,596.98
- The (All) member for CY2008 is \$16,038,062.60
- The (All) member for Pacific is \$1,594,335.38

Aggregations like this are pre-computed and stored in advance, which is part of the secret to fast query performance of Analysis Services.

Reseller Sales Amount	Column Labels				
Row Labels	▼ CY 2005	⊕ CY 2006	⊕ CY 2007	⊕ CY 2008	Grand Total
⊕ Europe		\$1,698,880.94	\$5,632,816.55	\$3,538,837.31	\$10,870,534.80
⊕ North America	\$8,065,435.31	\$22,445,548.71	\$25,722,421.91	\$11,752,320.88	\$67,985,726.81
⊕ Pacific			\$847,430.96	\$746,904.41	\$1,594,335.38
Grand Total	\$8,065,435.31	\$24,144,429.65	\$32,202,669.43	\$16,038,062.60	\$80,450,596.98

Expand the hierarchy, and eventually you get to the lowest level. This is called the **leaf member**. A leaf member is a member of a hierarchy that has no children. In this example, Southwest is the leaf member.

Reseller Sales Amount	Column Labels				
Row Labels	▼ CY 2005	⊕ CY 2006	⊕ CY 2007	⊕ CY 2008	Grand Total
⊕ Europe		\$1,698,880.94	\$5,632,816.55	\$3,538,837.31	\$10,870,534.80

Anything above it is called a **parent member**. United States is the parent of Southwest.

Components of an attribute hierarchy

Together, all these concepts build towards the concept of an **attribute hierarchy**. An attribute hierarchy is a tree of attribute members containing the following levels:

- A leaf level that contains each distinct attribute member, with each member of the leaf level also known as a **leaf member**.
- Intermediate levels if the attribute hierarchy is a parent-child hierarchy (more on that later).
- An (All) member that contains the aggregated value of all the child attributes. Optionally, you can hide or turn off the (All) level when it doesn't make sense for the data. For example, although Product Code is numeric, it wouldn't make sense to sum or average or otherwise aggregate all of the Product Codes.

① Note

BI developers often set properties on the attribute hierarchy to achieve certain behaviors in client applications, or gain certain performance benefits. For example, you would set AttributeHierarchyEnabled=False on attributes for which the (All)

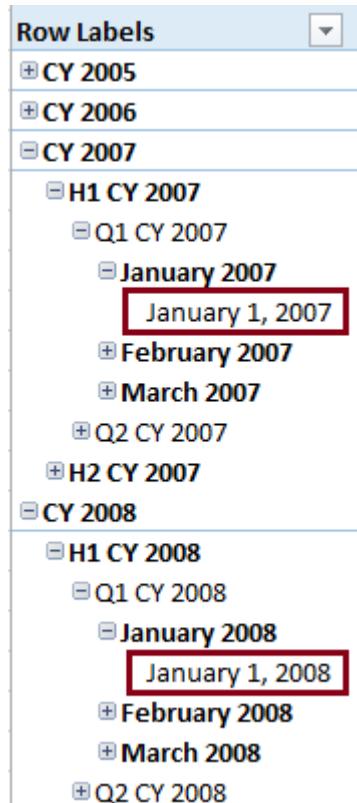

member doesn't make sense. Alternatively, perhaps you simply want to hide the (All) member, in which case you would set AttributeHierarchyVisible=False. See [Dimension Attribute Properties Reference](#) for more details about properties.

Navigation Hierarchies

Within the PivotTable (at least in this example), row and column axes expand to show lower levels of attributes. An expandable tree is achieved through navigation hierarchies that you create in a model. In the AdventureWorks sample model, the Sales Territory dimension has a multi-level hierarchy that begins with a Country Group, followed by Country, followed by Region.

As you can see, hierarchies are used to provide a navigation path in a PivotTable or other data summarization objects. There are two basic types: balanced and unbalanced.

Balanced Hierarchies

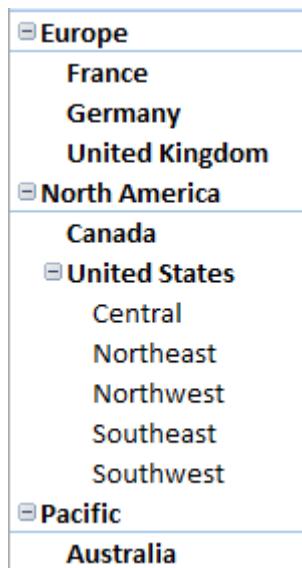

A **balanced hierarchy** is a hierarchy in which the same number of levels exists between the top level and any leaf member.

A **natural hierarchy** is one that emerges naturally from the underlying data. A common example is Country-Region-State or Year-Month-Date or Category-Subcategory-Model, where each subordinate level flows predictably from the parent.

In a multidimensional model, most hierarchies are balanced hierarchies, and many of them are also natural hierarchies.

Another related modeling term is a **user-defined hierarchy**, often used as a contrast with attribute hierarchies. It simply means a hierarchy created by the BI developer, as opposed to attribute hierarchies that are automatically generated by Analysis Services when you define an attribute.

Unbalanced Hierarchies

A **ragged hierarchy** or **unbalanced hierarchy** is a hierarchy in which different numbers of levels exist between the top level and the leaf members. Again, it's a hierarchy created by the BI developer, but in this case there are gaps in the data.

In the AdventureWorks sample model, Sales Territory illustrates a ragged hierarchy because the United States has an additional level (Regions) that does not exist for other countries/regions in this example.

Ragged hierarchies are a challenge to BI developers if the client application does not handle ragged hierarchies in an elegant manner. In Analysis Services model, you can build a **parent-child hierarchy** that explicitly defines a relationship among multi-level data, eliminating any ambiguity as to how one level relates to the next. See [Parent-Child Dimensions](#) for details.

Key Attributes

Models are a collection of related objects that rely on keys and indexes to make the associations. Analysis Services models are no different. For each dimension (recall it is equivalent to a table in a relational model), there is a key attribute. The **key attribute** is

used in foreign key relationships to the fact table (measure group). All non-key attributes in the dimension are linked (directly or indirectly) to the key attribute.

Often, but not always, the key attribute is also the **Granularity Attribute**. Granularity refers to the level of detail or precision within the data. Again, a common example offers the quickest path to understanding. Consider date values: For daily sales, you need date values specified to the day; for quotas, quarterly might be sufficient, but if your analytical data consists of race results from a sporting event, the grain might very well need to be milliseconds. The level of precision in your data values is the grain.

Currency is another example: a financial application might track monetary values out to many decimal places, whereas your local school's fund raiser might only need values to the nearest dollar. Understanding grain is important because you want to avoid storing unnecessary data. Trimming milliseconds from a timestamp, or pennies from a sales amount, can save storage and processing time when that level of detail is not relevant to your analysis.

To set the granularity attribute, use the Dimension Usage tab in Cube Designer in SQL Server Data Tools. In the AdventureWorks sample model, the key attribute of the Date dimension is the Date key. For Sales Orders, the granularity attribute is equivalent to the key attribute. For Sales Targets, the level of granularity is quarterly, and so the granularity attribute is set to Calendar Quarter, accordingly.

Dimensions		Measure Groups	
		Sales Orders	Sales Targets
Date		Date	Calendar Quarter

ⓘ Note

If the granularity attribute and the key attribute are different, all non-key attributes must be linked, directly or indirectly, to the granularity attribute. Within a cube, the granularity attribute defines a dimension's granularity.

Query Scope (Cube Space)

Scope of a query refers to the boundaries within which data is being selected. It can range from the entire cube (a cube is the largest query object) to a cell.

Cube space is the product of the members of a cube's attribute hierarchies with the cube's measures.

Subcube is a subset of a cube that represents a filtered view of the cube. Subcubes can be defined with a Scope statement in the MDX calculation script, or in a subselect clause in an MDX query or as a session cube.

Cell refers to the space at the intersection of a member of the measures dimension member and a member from each attribute hierarchy in a cube.

Other Modeling Terms

This section is a collection of concepts and terms that don't fit easily into other sections, but you still need to know about.

Calculated member is a dimension member that is defined and calculated at query time. A calculated member can be defined in a user query or in the MDX calculation script and stored on the server. A calculated member corresponds to rows in the dimension table of the dimension in which it is defined.

Distinct Count is a special type of measure used for data items that should only be counted once. The AdventureWorks sample model includes distinct count measures for Internet Orders, Reseller Orders, and Sales Orders.

Measure groups are a collection of one or more measures. Mostly these are user-defined, and you use them to keep related measures together. Distinct count measures are an exception. These are always placed in a dedicated measure group that contains only the distinct measure. You can't see the measure group in the PivotTable example illustration, but it does appear in a PivotTable field list, as a named collection of measures.

Measures dimension is the dimension that contains all of the measures in a cube. It's not exposed in a multidimensional model that you build in SQL Server Data Tools, but it exists just the same. Because it contains measures, all of the members of a measures dimension are typically aggregated (generally by sum or by count).

Database Dimensions and Cube Dimensions. Within a model, you can define standalone dimensions that are then included in any number of cubes in the same model. When you add a dimension to a cube, it's called a cube dimension. By itself within a project, as a standalone item in Object Explorer, it's called a database dimension. Why make the distinction? Because you can set properties on them independently. In product documentation, you'll see both terms used, so it's worthwhile to understand what they mean.

Next Steps

Now that you have a grasp of important concepts and terminology, you can continue on to these additional topics that further explain fundamental concepts in Analysis Services:

- [The Basic MDX Query \(MDX\)](#)
- [The Basic MDX Script \(MDX\)](#)
- [Multidimensional Modeling \(Adventure Works Tutorial\)](#)

Autoexists

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The concept of *autoexists* limits the cube space to those cells that actually exist in the cube in contraposition to those that might exist as a result of creating all possible combinations of attribute hierarchy members from the same hierarchy. This is because members of one attribute hierarchy cannot exist with members of another attribute hierarchy in the same dimension. When two or more attribute hierarchies of the same dimension are used in a SELECT statement, Analysis Services evaluates the attributes' expressions to make sure that the members of those attributes are properly confined to meet the criteria of all other attributes.

For example, suppose you are working with attributes from the Geography dimension. If you have one expression that returns all members from the City attribute and another expression that confines members from the Country attribute to all countries/regions in Europe, then this will result in the City members being confined to only those cities that belong to countries/regions in Europe. This is because of the autoexists characteristic of Analysis Services. Autoexists only applies to attributes from the same dimension because it tries to prevent the dimension records excluded in one attribute expression from being included by the other attribute expressions. Autoexists can also be understood as the resulting intersection of the different attributes expressions over the dimension rows.

Cell Existence

The following cells always exist:

- The (All) member, of every hierarchy, when crossed with members of other hierarchies in the same dimension.
- Calculated members when crossed with their non-calculated siblings, or with the parents or descendants of their non-calculated siblings.

Providing Non-existing cells

A non-existing cell is a cell provided by the system as a response to a query or calculation that requests a cell that does not exist in the cube. For example, if you have a

cube that has a City attribute hierarchy and a Country attribute hierarchy that belong to the Geography dimension, and an Internet Sales Amount measure, the space of this cube only includes those members that exist with each other. For example, if the City attribute hierarchy includes the cities New York, London, Paris, Tokyo, and Melbourne; and the Country attribute hierarchy includes the countries/regions United States, United Kingdom, France, Japan, and Australia; then the space of the cube does not include the space (cell) at the intersection of Paris and United States.

When querying cells that do not exist, non-existing cells return nulls; that is, they cannot contain calculations and you cannot define a calculation that writes to this space. For example, the following statement includes cells that do not exist.

```
SELECT [Customer].[Gender].[Gender].Members ON COLUMNS,  
{[Customer].[Customer].[Aaron A. Allen]  
,[Customer].[Customer].[Abigail Clark]} ON ROWS  
FROM [Adventure Works]  
WHERE Measures.[Internet Sales Amount]
```

ⓘ Note

This query uses the [Members \(Set\) \(MDX\)](#) function to return the set of members of the Gender attribute hierarchy on the column axis, and crosses this set with the specified set of members from the Customer attribute hierarchy on the row axis.

When you execute the previous query, the cell at the intersection of Aaron A. Allen and Female displays a null. Similarly, the cell at the intersection of Abigail Clark and Male displays a null. These cells do not exist and cannot contain a value, but cells that do not exist can appear in the result returned by a query.

When you use the [Crossjoin \(MDX\)](#) function to return the cross-product of attribute hierarchy members from attribute hierarchies in the same dimension, auto-exists limits those tuples being returned to the set of tuples that actually exist, rather than returning a full Cartesian product. For example, run and then examine the results from the execution of the following query.

```
SELECT CROSSJOIN  
(  
 {[Customer].[Country].[United States]},  
 [Customer].[State-Province].Members  
) ON 0
```

```
FROM [Adventure Works]
WHERE Measures.[Internet Sales Amount]
```

ⓘ Note

Notice that 0 is used to designate the column axis, which is shorthand for axis(0) - which is the column axis.

The previous query only returns cells for members from each attribute hierarchy in the query that exist with each other. The previous query can also be written using the new * variant of the [* \(Crossjoin\) \(MDX\)](#) function.

```
SELECT
    [Customer].[Country].[United States] *
    [Customer].[State-Province].Members
ON 0
FROM [Adventure Works]
WHERE Measures.[Internet Sales Amount]
```

The previous query could also be written in the following manner:

```
SELECT [Customer].[State-Province].Members
ON 0
FROM [Adventure Works]
WHERE (Measures.[Internet Sales Amount],
[Customer].[Country].[United States])
```

The cells values returned will be identical, although the metadata in the result set will be different. For example, with the previous query, the Country hierarchy was moved to the slicer axis (in the WHERE clause) and therefore does not appear explicitly in the result set.

Each of these three previous queries demonstrates the effect of the auto-exists behavior in SQL Server SQL Server Analysis Services.

Deep and Shallow Autoexists

Autoexists can be applied to the expressions as Deep or Shallow. **Deep Autoexists** means that all expressions will be evaluated to meet the deepest possible space after

applying the slicer expressions, the sub select expressions in the axis, and so on. **Shallow Autoexists** means that external expressions are evaluated before the current expression and those results are passed to the current expression. The default setting is deep autoexists.

The following scenario and samples will help to illustrate the different types of Autoexistss. In the following examples two sets will be created: one as a calculated expression and the other as a constant expression.

```
//Obtain the Top 10 best reseller selling products by Name

with member [Measures].[PCT Discount] AS '[Measures].[Discount Amount]/[Measures].[Reseller Sales Amount]', FORMAT_STRING = 'Percent'

set Top10SellingProducts as 'topcount([Product].[Model Name].children, 10,
[Measures].[Reseller Sales Amount])'

set Preferred10Products as '

{[Product].[Model Name].&[Mountain-200], 

[Product].[Model Name].&[Road-250], 

[Product].[Model Name].&[Mountain-100], 

[Product].[Model Name].&[Road-650], 

[Product].[Model Name].&[Touring-1000], 

[Product].[Model Name].&[Road-550-W], 

[Product].[Model Name].&[Road-350-W], 

[Product].[Model Name].&[HL Mountain Frame], 

[Product].[Model Name].&[Road-150], 

[Product].[Model Name].&[Touring-3000]

}

select {[Measures].[Reseller Sales Amount], [Measures].[Discount Amount],
[Measures].[PCT Discount]} on 0,
Top10SellingProducts on 1
```

```
from [Adventure Works]
```

The obtained result set is:

[\[+\] Expand table](#)

	Reseller Sales Amount	Discount Amount	PCT Discount
Mountain-200	\$14,356,699.36	\$19,012.71	0.13%
Road-250	\$9,377,457.68	\$4,032.47	0.04%
Mountain-100	\$8,568,958.27	\$139,393.27	1.63%
Road-650	\$7,442,141.81	\$39,698.30	0.53%
Touring-1000	\$6,723,794.29	\$166,144.17	2.47%
Road-550-W	\$3,668,383.88	\$1,901.97	0.05%
Road-350-W	\$3,665,932.31	\$20,946.50	0.57%
HL Mountain Frame	\$3,365,069.27	\$174.11	0.01%
Road-150	\$2,363,805.16	\$0.00	0.00%
Touring-3000	\$2,046,508.26	\$79,582.15	3.89%

The obtained set of products seems to be the same as Preferred10Products; so, verifying the Preferred10Products set:

```
with member [Measures].[PCT Discount] AS '[Measures].[Discount Amount]/[Measures].[Reseller Sales Amount]', FORMAT_STRING = 'Percent'

set Top10SellingProducts as 'topcount([Product].[Model Name].children, 10,
[Measures].[Reseller Sales Amount])'

set Preferred10Products as '

{[Product].[Model Name].&[Mountain-200], 

[Product].[Model Name].&[Road-250], 

[Product].[Model Name].&[Mountain-100], 

[Product].[Model Name].&[Road-650], 

[Product].[Model Name].&[Touring-1000],
```

```

[Product].[Model Name].&[Road-550-W],  

[Product].[Model Name].&[Road-350-W],  

[Product].[Model Name].&[HL Mountain Frame],  

[Product].[Model Name].&[Road-150],  

[Product].[Model Name].&[Touring-3000]  

}'  

select {[Measures].[Reseller Sales Amount], [Measures].[Discount Amount],  

[Measures].[PCT Discount]} on 0,  

Preferred10Products on 1  

from [Adventure Works]

```

As per the following results, both sets (Top10SellingProducts, Preferred10Products) are the same

[Expand table](#)

	Reseller Sales Amount	Discount Amount	PCT Discount
Mountain-200	\$14,356,699.36	\$19,012.71	0.13%
Road-250	\$9,377,457.68	\$4,032.47	0.04%
Mountain-100	\$8,568,958.27	\$139,393.27	1.63%
Road-650	\$7,442,141.81	\$39,698.30	0.53%
Touring-1000	\$6,723,794.29	\$166,144.17	2.47%
Road-550-W	\$3,668,383.88	\$1,901.97	0.05%
Road-350-W	\$3,665,932.31	\$20,946.50	0.57%
HL Mountain Frame	\$3,365,069.27	\$174.11	0.01%
Road-150	\$2,363,805.16	\$0.00	0.00%
Touring-3000	\$2,046,508.26	\$79,582.15	3.89%

The following example will illustrate the concept of deep Autoexists. In the example we are filtering Top10SellingProducts by [Product].[Product Line] attribute for those in

[Mountain] group. Note that both attributes (slicer and axis) belong to the same dimension, [Product].

```
with member [Measures].[PCT Discount] AS '[Measures].[Discount Amount]/[Measures].[Reseller Sales Amount]', FORMAT_STRING = 'Percent'

set Top10SellingProducts as 'topcount([Product].[Model Name].children, 10,
[Measures].[Reseller Sales Amount])'

// Preferred10Products set removed for clarity

select {[Measures].[Reseller Sales Amount], [Measures].[Discount Amount],
[Measures].[PCT Discount]} on 0,
Top10SellingProducts on 1

from [Adventure Works]

where [Product].[Product Line].[Mountain]
```

Produces the following result set:

[Expand table](#)

	Reseller Sales Amount	Discount Amount	PCT Discount
Mountain-200	\$14,356,699.36	\$19,012.71	0.13%
Mountain-100	\$8,568,958.27	\$139,393.27	1.63%
HL Mountain Frame	\$3,365,069.27	\$174.11	0.01%
Mountain-300	\$1,907,249.38	\$876.95	0.05%
Mountain-500	\$1,067,327.31	\$17,266.09	1.62%
Mountain-400-W	\$592,450.05	\$303.49	0.05%
LL Mountain Frame	\$521,864.42	\$252.41	0.05%
ML Mountain Frame-W	\$482,953.16	\$206.95	0.04%
ML Mountain Frame	\$343,785.29	\$161.82	0.05%
Women's Mountain Shorts	\$260,304.09	\$6,675.56	2.56%

In the above result set we have seven newcomers to the list of Top10SellingProducts and Mountain-200, Mountain-100, and HL Mountain Frame have moved to the top of

the list. In the previous result set those three values were interspersed.

This is called Deep Autoexists, because the Top10SellingProducts set is evaluated to meet the slicing conditions of the query. Deep Autoexists means that all expressions will be evaluated to meet the deepest possible space after applying the slicer expressions, the sub select expressions in the axis, and so on.

However, one might want to be able to do the analysis over the Top10SellingProducts as equivalent to Preferred10Products, as in the following example:

```
with member [Measures].[PCT Discount] AS '[Measures].[Discount Amount]/[Measures].  
[Reseller Sales Amount]', FORMAT_STRING = 'Percent'  
  
set Top10SellingProducts as 'topcount([Product].[Model Name].children, 10,  
[Measures].[Reseller Sales Amount])'  
  
set Preferred10Products as '  
  
 {[Product].[Model Name].&[Mountain-200],  
[Product].[Model Name].&[Road-250],  
[Product].[Model Name].&[Mountain-100],  
[Product].[Model Name].&[Road-650],  
[Product].[Model Name].&[Touring-1000],  
[Product].[Model Name].&[Road-550-W],  
[Product].[Model Name].&[Road-350-W],  
[Product].[Model Name].&[HL Mountain Frame],  
[Product].[Model Name].&[Road-150],  
[Product].[Model Name].&[Touring-3000]  
}'  
  
select {[Measures].[Reseller Sales Amount], [Measures].[Discount Amount],  
[Measures].[PCT Discount]} on 0,  
Preferred10Products on 1  
  
from [Adventure Works]
```

```
where [Product].[Product Line].[Mountain]
```

Produces the following result set:

[+] Expand table

	Reseller Sales Amount	Discount Amount	PCT Discount
Mountain-200	\$14,356,699.36	\$19,012.71	0.13%
Mountain-100	\$8,568,958.27	\$139,393.27	1.63%
HL Mountain Frame	\$3,365,069.27	\$174.11	0.01%

In the above results, the slicing gives a result that contains only those products from Preferred10Products that are part of the [Mountain] group in [Product].[Product Line]; as expected, because Preferred10Products is a constant expression.

This result set is also understood as Shallow Autoexists. This is because the expression is evaluated before the slicing clause. In the previous example, the expression was a constant expression for illustration purposes in order to introduce the concept.

Autoexists behavior can be modified at the session level using the **Autoexists** connection string property. The following example begins by opening a new session and adding the *Autoexists=3* property to the connection string. You must open a new connection in order to do the example. Once the connection is established with the Autoexist setting it will remain in effect until that connection is finished.

```
with member [Measures].[PCT Discount] AS '[Measures].[Discount Amount]/[Measures].[Reseller Sales Amount]', FORMAT_STRING = 'Percent'

set Top10SellingProducts as 'topcount([Product].[Model Name].children, 10,
[Measures].[Reseller Sales Amount])'

//Preferred10Products set removed for clarity

select {[Measures].[Reseller Sales Amount], [Measures].[Discount Amount],
[Measures].[PCT Discount]} on 0,
Top10SellingProducts on 1

from [Adventure Works]

where [Product].[Product Line].[Mountain]
```

The following result set now shows the shallow behavior of Autoexists.

	Reseller Sales Amount	Discount Amount	PCT Discount
Mountain-200	\$14,356,699.36	\$19,012.71	0.13%
Mountain-100	\$8,568,958.27	\$139,393.27	1.63%
HL Mountain Frame	\$3,365,069.27	\$174.11	0.01%

Autoexists behavior can be modified by using the AUTOEXISTS=[1|2|3] parameter in the connection string; see [Supported XMLA Properties \(XMLA\)](#) and [ConnectionString](#) for parameter usage.

Calculation Context

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The calculation context is the known subspace of the cube where an expression is evaluated and all coordinates are either explicitly known or can be derived from the expression.

Determining the calculation context

Every set, member, tuple, or numeric function executes in the context of the entire MDX expression or statement. When an argument, such as a tuple, is passed to a function, only some of the coordinates in the cube space are explicitly provided. The other coordinates are obtained based on the current calculation context.

The calculation context for unspecified cell coordinates and attribute members is determined in the following order:

1. The FROM clause (if applicable) - this clause can either specify an entire cube or can specify a subcube in the form of a SELECT statement.
2. The WHERE clause (if applicable) - this clause, which is also known as the *slicer axis*, on which you specify a set, tuple, or member that restricts the members returned on the column and row axis by a query. Conceptually, the default member of every attribute hierarchy that is not explicitly specified on column or row axis is part of the slicer axis.

Note

When cell coordinates for a particular attribute are specified on both the slicer axis and on another axis, the coordinates specified in the function may take precedence in determining the members of the set on the axis. The [Filter \(MDX\)](#) and [Order \(MDX\)](#) functions are examples of such functions - you can filter or order a result by attribute members that are excluded from the calculation context by the WHERE clause, or by a SELECT statement in the FROM clause.

3. The named sets and calculated members defined in the query or expression.

4. The tuples and sets specified on the row and column axes, utilizing the default member for attributes that do not appear on the row, column, or slicer axis.
5. The cube or subcube cells on each axis, eliminating empty tuples on the axis and applying the HAVING clause.
6. For more information, see [Establishing Cube Context in a Query \(MDX\)](#).

In the following query, the calculation context for the row axis is restricted by the Country attribute member and the Calendar Year attribute member that are specified in the WHERE clause.

```
SELECT Customer.City.City.Members ON 0
FROM [Adventure Works]
WHERE (Customer.Country.France, [Date].[Calendar].[Calendar Year].[CY 2004],
      Measures.[Internet Sales Amount])
```

However, if you modify this query by specifying the **FILTER** function on the row axis, and utilize a Calendar Year attribute hierarchy member in the **FILTER** function, then the attribute member from the Calendar Year attribute hierarchy that is used to provide the calculation context for the members of the set on the column axis can be modified.

```
SELECT FILTER
(
  Customer.City.City.Members,
  ([Date].[Calendar].[Calendar Year].[CY 2003],
   Measures.[Internet Order Quantity]) > 75
) ON 0
FROM [Adventure Works]
WHERE (Customer.Country.France,
      [Date].[Calendar].[Calendar Year].[CY 2004],
      Measures.[Internet Sales Amount])
```

In the previous query, the calculation context for the cells in the tuples that appear on the column axis is filtered by the CY 2003 member of the Calendar Year attribute hierarchy, even though the nominal calculation context for the Calendar Year attribute hierarchy is CY 2004. Furthermore, it is filtered by the Internet Order Quantity measure. However, once the members of the set on the column axis is set, the calculation context for the values for the members that appear on the axis is again determined by the WHERE clause.

Important

To increase query performance, you should eliminate members and tuples as early in the resolution process as possible. In this manner, complex query time calculations on the final set of members operate on the fewest cells possible.

Calculated Members in Subselects and Subcubes

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A calculated member is a dimension member whose value is calculated from an expression at run time, and can be used in subselects and subcubes to more precisely define the cubespace of a query.

Enabling calculated members in the subspace

The **SubQueries** connection string property in [ConnectionString](#) or the **DBPROPMSMDSUBQUERIES** property in [Supported XMLA Properties \(XMLA\)](#) defines the behavior or allowance of calculated members or calculated sets on subselects or subcubes. In the context of this document, subselect refers to subselects and subcubes unless otherwise stated.

The SubQueries property allows the following values.

 [Expand table](#)

Value	Description
0	Calculated members are not allowed in subselects or subcubes. An error is raised when evaluating the subselect or subcube if a calculated member is referenced.
1	Calculated members are allowed in subselects or subcubes but no ascendant members are introduced in the returning subspace.
2	Calculated members are allowed in subselects or subcubes and ascendant members are introduced in the returning subspace. Also, mixed granularity is allowed in the selection of calculated members.

Using values of 1 or 2 in the SubQueries property allows calculated members to be used to filter the returning subspace of subselects.

An example will help clarify the concept; first a calculated member must be created and then a subselect query issued to show the above mentioned behavior.

The following sample creates a calculated member that adds [Seattle Metro] as a city to the [Geography].[Geography] hierarchy under Washington state.

To run the example, the connection string must contain the SubQueries property with a value of 1 and all MDX statements must be run in the same session.

Important

If you're using Management Studio to test the queries, click the Options button on Connection Manager to access the additional connection string properties pane, where you can enter subqueries=1 or 2 to allow calculated members in the subspace.

First issue the following MDX expression:

```
CREATE MEMBER [Adventure Works].[Geography].[Geography].[State-Province].&
[WA]&[US].[Seattle Metro Agg]
AS AGGREGATE(
{
    [Geography].[Geography].[City].&[Bellevue]&[WA]
    , [Geography].[Geography].[City].&[Issaquah]&[WA]
    , [Geography].[Geography].[City].&[Redmond]&[WA]
    , [Geography].[Geography].[City].&[Seattle]&[WA]
}
)
```

Then issue the following MDX query to see calculated members allowed in subselects.

```
Select [Date].[Calendar Year].members on 0,
[Geography].[Geography].allmembers on 1
from (Select {[Geography].[Geography].[State-Province].&[WA]&[US].[Seattle
Metro Agg]} on 0 from [Adventure Works])
Where [Measures].[Reseller Sales Amount]
```

The obtained results are:

 Expand table

	All Periods	CY 2011	CY 2012	CY 2013	CY 2014
Seattle Metro Agg	\$2,383,545.69	\$1,291,248.93	\$763,557.02	\$915,832.36	\$412,907.37

As said before, the descendants of [Seattle Metro] do not exist in the returned subspace, when SubQueries=1, hence [Geography].[Geography].allmembers only contains the calculated member.

If the example is run using SubQueries=2, in the connection string, the obtained results are:

[\[+\] Expand table](#)

	All Periods	CY 2001	CY 2002	CY 2003	CY 2004
All Geographies	(null)	(null)	(null)	(null)	(null)
United States	(null)	(null)	(null)	(null)	(null)
Washington	(null)	(null)	(null)	(null)	(null)
Seattle Metro Agg	\$2,383,545.69	\$291,248.93	\$763,557.02	\$915,832.36	\$412,907.37

As said before, when using SubQueries=2, the descendants of [Seattle Metro] exist in the returned subspace but no values exist for those members because there is no regular members to provide for the aggregations. Therefore, NULL values are provided for all descendant members of the calculated member in this example.

To understand the above behavior, it helps to understand that calculated members do not contribute to the aggregations of their parents as regular members do; the former implies that filtering by calculated members alone will lead to empty descendants because there are no regular members to contribute to the aggregated values of the resulting subspace. If you add regular members to the filtering expression then the aggregated values will come from those regular members. Continuing with the above example, if the cities of Portland, in Oregon, and the city of Spokane, in Washington, are added to the same axis where the calculated member appears; as shown in the next MDX expression:

```
Select [Date].[Calendar Year].members on 0,
      [Geography].[Geography].allmembers on 1
from (Select {
            [Seattle Metro Agg]
            , [Geography].[Geography].[City].&[Portland]&[OR]
            , [Geography].[Geography].[City].&[Spokane]&[WA]
        } on 0 from [Adventure Works]
    )
Where [Measures].[Reseller Sales Amount]
```

The following results are obtained.

[] Expand table

	All Periods	CY 2001	CY 2002	CY 2003	CY 2004
All Geographies	\$235,171.62	\$419.46	\$4,996.25	\$131,788.82	\$97,967.09
United States	\$235,171.62	\$419.46	\$4,996.25	\$131,788.82	\$97,967.09
Oregon	\$30,968.25	\$419.46	\$4,996.25	\$17,442.97	\$8,109.56
Portland	\$30,968.25	\$419.46	\$4,996.25	\$17,442.97	\$8,109.56
97205	\$30,968.25	\$419.46	\$4,996.25	\$17,442.97	\$8,109.56
Washington	\$204,203.37	(null)	(null)	\$114,345.85	\$89,857.52
Spokane	\$204,203.37	(null)	(null)	\$114,345.85	\$89,857.52
99202	\$204,203.37	(null)	(null)	\$114,345.85	\$89,857.52
Seattle Metro Agg	\$2,383,545.69	\$291,248.93	\$763,557.02	\$915,832.36	\$412,907.37

In the above results the aggregated values for [All Geographies], [United States], [Oregon] and [Washington] come from aggregating over the descendants of & [Portland]&[OR] and &[Spokane]&[WA]. Nothing comes from the calculated member.

Remarks

Only global or session calculated members are allowed in the subselect or subcube expressions. Having query calculated members in the MDX expression will raise an error when the subselect or subcube expression is evaluated.

Cube Space

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Cube space is the product of the members of a cube's attribute hierarchies with the cube's measures. Therefore, the cube space is determined by the combinatorial product of all attribute hierarchy members in the cube and the cube's measures and defines the maximum size of the cube. It is important to note that this space includes all possible combinations of attribute hierarchy members; even combinations that might be deemed as impossible in the real world i.e. combinations where the city is Paris and the countries/regions are England or Spain or Japan or India or elsewhere.

Autoexists and cube space

The concept of *autoexists* limits this cube space to those cells that actually exist. Members of an attribute hierarchy in a dimension may not exist with members of another attribute hierarchy in the same dimension.

For example, if you have a cube that has a City attribute hierarchy, a Country attribute hierarchy, and an Internet Sales Amount measure, the space of this cube only includes those members that exist with each other. For example, if the City attribute hierarchy includes the cities New York, London, Paris, Tokyo, and Melbourne; and the Country attribute hierarchy includes the countries/regions United States, United Kingdom, France, Japan, and Australia; then the space of the cube does not include the space (cell) at the intersection of Paris and United States.

When querying cells that do not exist, non-existing cells return nulls; that is, they cannot contain calculations and you cannot define a calculation that writes to this space. For example, the following statement includes cells that do not exist.

```
SELECT [Customer].[Gender].[Gender].Members ON COLUMNS,  
{[Customer].[Customer].[Aaron A. Allen]  
,[Customer].[Customer].[Abigail Clark]} ON ROWS  
FROM [Adventure Works]  
WHERE Measures.[Internet Sales Amount]
```

Note

This query uses the [Members \(Set\) \(MDX\)](#) function to return the set of members of the Gender attribute hierarchy on the column axis, and crosses this set with the specified set of members from the Customer attribute hierarchy on the row axis.

When you execute the previous query, the cell at the intersection of Aaron A. Allen and Female displays a null. Similarly, the cell at the intersection of Abigail Clark and Male displays a null. These cells do not exist and cannot contain a value, but cells that do not exist can appear in the result returned by a query.

When you use the [Crossjoin \(MDX\)](#) function to return the cross-product of attribute hierarchy members from attribute hierarchies in the same dimension, auto-exists limits those tuples being returned to the set of tuples that actually exist, rather than returning a full Cartesian product. For example, run and then examine the results from the execution of the following query.

```
SELECT CROSSJOIN
(
    {[Customer].[Country].[United States]},
    [Customer].[State-Province].Members
) ON 0
FROM [Adventure Works]
WHERE Measures.[Internet Sales Amount]
```

① Note

Notice that 0 is used to designate the column axis, which is shorthand for axis(0) - which is the column axis.

The previous query only returns cells for members from each attribute hierarchy in the query that exist with each other. The previous query can also be written using the new * variant of the [* \(Crossjoin\) \(MDX\)](#) function.

```
SELECT
[Customer].[Country].[United States] *
[Customer].[State-Province].Members
ON 0
FROM [Adventure Works]
WHERE Measures.[Internet Sales Amount]
```

The previous query could also be written in the following manner:

```
SELECT [Customer].[State-Province].Members
ON 0
FROM [Adventure Works]
WHERE (Measures.[Internet Sales Amount],
[Customer].[Country].[United States])
```

The cells values returned will be identical, although the metadata in the result set will be different. For example, with the previous query, the Country hierarchy was moved to the slicer axis (in the WHERE clause) and therefore does not appear explicitly in the result set.

Each of these three previous queries demonstrates the effect of the auto-exists behavior in SQL Server SQL Server Analysis Services.

User-Defined Hierarchies and Cube Space

The previous examples in this topic define positions in cube space by using attribute hierarchies. However, you can also define a position in cube space by using user-defined hierarchies that have been defined based on attribute hierarchies in a dimension. A user-defined hierarchy is a hierarchy of attribute hierarchies designed to facilitate browsing of cube data by users.

For example, the **CROSSJOIN** query in the previous section could also have been written as follows:

```
SELECT CROSSJOIN
(
    {[Customer].[Country].[United States]},
    [Customer].[Customer Geography].[State-Province].Members
)
ON 0
FROM [Adventure Works]
WHERE Measures.[Internet Sales Amount]
```

In the previous query, the Customer Geography user-defined hierarchy within the Customer dimension is used to define the position in cube space that was previously defined by using an attribute hierarchy. The identical position in cube space can be defined by using either attribute hierarchies or user-defined hierarchies.

Attribute Relationships and Cube Space

Defining attribute relationships between related attributes improves query performance (by facilitating the creation of appropriate aggregations) and affects the member of a related attribute hierarchy that appears with an attribute hierarchy member. For example, when you define a tuple that includes a member from the City attribute hierarchy and the tuple does not explicitly define the Country attribute hierarchy member, you might expect that the default Country attribute hierarchy member would be the related member of the Country attribute hierarchy. However, this is only true if an attribute relationship is defined between the City attribute hierarchy and the Country attribute hierarchy.

The following example returns the member of a related attribute hierarchy that is not included explicitly in the query.

```
WITH MEMBER Measures.x AS  
    Customer.Country.CurrentMember.Name  
SELECT Measures.x ON 0,  
Customer.City.Members ON 1  
FROM [Adventure Works]
```

① Note

Notice that the **WITH** keyword is used with the [CurrentMember \(MDX\)](#) and [Name \(MDX\)](#) functions to create a calculated member for use in the query. For more information, see [The Basic MDX Query \(MDX\)](#).

In the previous query, the name of the member of the Country attribute hierarchy that is associated with each member of the State attribute hierarchy is returned. The expected Country member appears (because an attribute relationship is defined between the City and Country attributes). However, if no attribute relationship were defined between attribute hierarchies in the same dimension, the (All) member would be returned, as illustrated in the following query.

```
WITH MEMBER Measures.x AS  
    Customer.Education.Currentmember.Name  
SELECT Measures.x ON 0,  
Customer.City.Members ON 1  
FROM [Adventure Works]
```

In the previous query, the (All) member ("All Customers") is returned, because there is no relationship between Education and City. Therefore, the (All) member of the Education attribute hierarchy would be the default member of the Education attribute hierarchy used in any tuple involving the City attribute hierarchy where an Education member is not explicitly provided.

Subselects in Queries

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Subselect expressions are nested SELECT expressions that are used to restrict the space of the cube from where the outer external SELECT is being evaluated. Subselects allow you to define a new space over which all calculations are evaluated.

Subselects by example

Let's begin with an example of how subselects can help to produce the results we want to show. Assume that you are requested to produce a table that shows the sales behavior, over years, for the top 10 products.

The result should look like the following table:

Expand table

	Sum of Years	Year 1	...
Sum of Top 10 Products			
Product A			
...			

To do something like the above one could write the following MDX expression:

```
SELECT [Date].[Calendar Year].MEMBERS on 0
    , TOPCOUNT( [Product].[Product].MEMBERS
        , 10
        , [Measures].[Sales Amount]
    ) ON 1
FROM [Adventure Works]
```

That returns the following results:

Expand table

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
All Products	\$80,450,596.98	\$8,065,435.31	\$24,144,429.65	\$32,202,669.43	\$16,038,062.60

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
Mountain-200 Black, 38	\$1,634,647.94	(null)	(null)	\$894,207.97	\$740,439.97
Mountain-200 Black, 42	\$1,285,524.65	(null)	(null)	\$722,137.65	\$563,387.00
Mountain-200 Silver, 38	\$1,181,945.82	(null)	(null)	\$634,600.78	\$547,345.03
Mountain-200 Black, 46	\$995,927.43	(null)	(null)	\$514,995.76	\$480,931.68
Mountain-200 Silver, 42	\$1,005,111.77	(null)	(null)	\$529,543.29	\$475,568.49
Mountain-200 Silver, 46	\$975,932.56	(null)	(null)	\$526,759.30	\$449,173.26
Road-150 Red, 56	\$792,228.98	\$382,159.24	\$410,069.74	(null)	(null)
Mountain-200 Black, 38	\$1,471,078.72	(null)	\$789,958.49	\$681,120.23	(null)
Road-350-W Yellow, 48	\$1,380,253.88	(null)	(null)	\$744,988.37	\$635,265.50

Which is very close to what we are looking for; except that the query returned 9 not 10 products and the All Products total reflects the sum of all products not the sum of the returned Top 9 (in this case). Another attempt to solve the problem is presented in the following MDX query:

```
SELECT [Date].[Calendar Year].MEMBERS on 0
    , TOPCOUNT( [Product].[Product].CHILDREN, 10, [Measures].[Sales Amount]) ON
1
FROM [Adventure Works]
```

That returns the following results:

[\[+\] Expand table](#)

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
Mountain-200 Black, 38	\$1,634,647.94	(null)	(null)	\$894,207.97	\$740,439.97
Mountain-200 Black, 42	\$1,285,524.65	(null)	(null)	\$722,137.65	\$563,387.00
Mountain-200 Silver, 38	\$1,181,945.82	(null)	(null)	\$634,600.78	\$547,345.03

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
Mountain-200 Black, 46	\$995,927.43	(null)	(null)	\$514,995.76	\$480,931.68
Mountain-200 Silver, 42	\$1,005,111.77	(null)	(null)	\$529,543.29	\$475,568.49
Mountain-200 Silver, 46	\$975,932.56	(null)	(null)	\$526,759.30	\$449,173.26
Road-150 Red, 56	\$792,228.98	\$382,159.24	\$410,069.74	(null)	(null)
Mountain-200 Black, 38	\$1,471,078.72	(null)	\$789,958.49	\$681,120.23	(null)
Road-350-W Yellow, 48	\$1,380,253.88	(null)	(null)	\$744,988.37	\$635,265.50
Road-150 Red, 62	\$566,797.97	\$234,018.86	\$332,779.11	(null)	(null)

That was very close to the desired result because it only missed the sum of the products. At this point one can start tweaking the above MDX expression to add the missing line; however, that task could prove to be a cumbersome one.

Another approach to solve the problem, would be to start thinking in terms of redefining the cube space over which the MDX expression is resolved. What if the 'new' cube contains only data from the Top 10 products? That cube then will have the All member adjusted to the Top 10 products only and now a simple query would resolve our needs.

The following MDX expression uses a subselect statement to redefine the cube space to the Top 10 products and produce the desired results:

```

SELECT [Date].[Calendar Year].MEMBERS on 0
    , [Product].[Product].MEMBERS on 1
    FROM (SELECT TOPCOUNT( [Product].[Product].CHILDREN
        , 10
        , [Measures].[Sales Amount]
    ) ON 0
    FROM [Adventure Works]
)
WHERE [Measures].[Sales Amount]

```

The above expression returns the following results:

[\[+\] Expand table](#)

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
All Products	\$19,997,183.30	\$1,696,815.63	\$2,816,611.28	\$7,930,797.72	\$7,552,958.66
Mountain-200 Silver, 38	\$2,160,981.60	(null)	(null)	\$1,024,359.10	\$1,136,622.49

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
Mountain-200 Silver, 42	\$1,914,547.85	(null)	(null)	\$903,061.68	\$1,011,486.18
Mountain-200 Silver, 46	\$1,906,248.55	(null)	(null)	\$877,077.79	\$1,029,170.76
Mountain-200 Black, 38	\$1,811,229.02	(null)	\$896,511.60	\$914,717.43	(null)
Mountain-200 Black, 38	\$2,589,363.78	(null)	(null)	\$1,261,406.37	\$1,327,957.41
Mountain-200 Black, 42	\$2,265,485.38	(null)	(null)	\$1,126,055.89	\$1,139,429.49
Mountain-200 Black, 46	\$1,957,528.24	(null)	(null)	\$946,453.88	\$1,011,074.37
Road-150 Red, 62	\$1,769,096.69	\$828,011.68	\$941,085.01	(null)	(null)
Road-150 Red, 56	\$1,847,818.63	\$868,803.96	\$979,014.67	(null)	(null)
Road-350-W Yellow, 48	\$1,774,883.56	(null)	(null)	\$877,665.59	\$897,217.96

The results above are exactly what we were looking for.

Let's review what exactly did the subselect do for us. The subselect returned for us a new cube that contained all other dimensions from product as they are; but, in the product dimension it filtered all members to match the top 10 products that we were interested in. It was as if we had removed all data that did not meet the Top 10 criteria and had rebuilt the cube. The other important concept to understand in this example is the fact that the Top 10 products were calculated over the All member of all the other dimensions in the cube; the former is true because no other filtering restrictions were imposed in the subselect.

Subselects can be as complex as one would like; the following example will illustrate how to produce a similar table as the mentioned above but filtered on France on the Sales Territory dimension and on Internet for the Sales Channel dimension.

```

SELECT [Date].[Calendar Year].MEMBERS on 0
    , [Product].[Product].MEMBERS on 1
    FROM (SELECT TOPCOUNT( [Product].[Product].CHILDREN
        , 10
        , [Measures].[Sales Amount]
    ) ON 0
        , [Sales Territory].[Sales Territory].[Region].[France] on 1
        , [Sales Channel].[Sales Channel].[Internet] on 2
    FROM [Adventure Works]

```

```

        )
WHERE [Measures].[Sales Amount]

```

Produced the following results:

[Expand table](#)

	All Periods	CY 2005	CY 2006	CY 2007	CY 2008
All Products	\$748,682.49	\$32,204.43	\$73,125.18	\$269,506.56	\$373,846.32
Mountain-200 Silver, 38	\$90,479.61	(null)	(null)	\$41,759.82	\$48,719.79
Mountain-200 Silver, 42	\$97,439.58	(null)	(null)	\$39,439.83	\$57,999.75
Mountain-200 Silver, 46	\$102,079.56	(null)	(null)	\$27,839.88	\$74,239.68
Mountain-200 Black, 38	\$26,638.28	(null)	\$12,294.59	\$14,343.69	(null)
Mountain-200 Black, 38	\$96,389.58	(null)	(null)	\$41,309.82	\$55,079.76
Mountain-200 Black, 42	\$80,324.65	(null)	(null)	\$43,604.81	\$36,719.84
Mountain-200 Black, 46	\$107,864.53	(null)	(null)	\$45,899.80	\$61,964.73
Road-150 Red, 62	\$46,517.51	\$14,313.08	\$32,204.43	(null)	(null)
Road-150 Red, 56	\$46,517.51	\$17,891.35	\$28,626.16	(null)	(null)
Road-350-W Yellow, 48	\$54,431.68	(null)	(null)	\$15,308.91	\$39,122.77

The above results are the Top 10 products sold in France through the Internet channel.

Subselect statement

The BNF for the Subselect is:

```

[WITH [<calc-clause> ...]]
SELECT [<axis-spec> [, <axis-spec> ...]]
FROM [<identifier> | (< sub-select-statement >)]
[WHERE <slicer>]
[[CELL] PROPERTIES <cellprop> [, <cellprop> ...]]

< sub-select-statement > :=
  SELECT [<axis-spec> [, <axis-spec> ...]]
  FROM [<identifier> | (< sub-select-statement >)]
  [WHERE <slicer>]

```

The subselect is another Select statement where the axis specifications and the slicer specification filter the space of the cube over which the outer select is evaluated.

When a member is specified in one of the axis or slicer clause then that member with its descendants and descendants are included in the sub cube space for the subselect; all non mentioned sibling members, in the axis or slicer clause, and their descendants are filtered from the subspace. This way, the space of the outer select has been limited to the existing members in the axis clause or slicer clause, with their descendants and descendants as mentioned before.

Because the All member of all non mentioned dimensions in axis or slicer clauses belongs to the space of the select; then, all descendants to the All member on those dimensions are, also, part of the subselect space.

The All member, in all dimensions, in the subcube space, is re-evaluated to reflect the impact of the constraints of the new space.

The following example will show what has been said above; the first MDX expression helps to display the unfiltered values in the cube, the second MDX illustrates the effect of filtering in the Subselect clause:

```
SELECT { [Customer].[Customer Geography].[All Customers]
    , [Customer].[Customer Geography].[Country].&[United States]
    , [Customer].[Customer Geography].[State-Province].&[OR]&[US]
    , [Customer].[Customer Geography].[City].&[Portland]&[OR]
    , [Customer].[Customer Geography].[State-Province].&[WA]&[US]
    , [Customer].[Customer Geography].[City].&[Seattle]&[WA]
} ON 1
, {[Measures].[Internet Sales Amount], [Measures].[Reseller Sales Amount]}
ON 0
FROM [Adventure Works]
```

Returns the following values:

[Expand table](#)

	Internet Sales Amount	Reseller Sales Amount
All Customers	\$29,358,677.22	\$80,450,596.98
United States	\$9,389,789.51	\$80,450,596.98
Oregon	\$1,170,991.54	\$80,450,596.98
Portland	\$110,649.54	\$80,450,596.98
Washington	\$2,467,248.34	\$80,450,596.98

	Internet Sales Amount	Reseller Sales Amount
Seattle	\$75,164.86	\$80,450,596.98

In the above example Seattle is a child of Washington, Portland is a child of Oregon, Oregon and Washington are children of United States and United States is a child of [Customer Geography].[All Customers]. All of the shown members in this example have other siblings that contribute to the parent aggregate value; i.e. Spokane, Tacoma and Everett are sibling cities of Seattle and they all contribute to Washington Internet Sales Amount. Reseller Sales Amount value is independent of Customer Geography attribute; hence the All value is displayed in the results. The next MDX expression illustrates the filtering effect of the subselect clause:

```

SELECT { [Customer].[Customer Geography].[All Customers]
    , [Customer].[Customer Geography].[Country].&[United States]
    , [Customer].[Customer Geography].[State-Province].&[OR]&[US]
    , [Customer].[Customer Geography].[City].&[Portland]&[OR]
    , [Customer].[Customer Geography].[State-Province].&[WA]&[US]
    , [Customer].[Customer Geography].[City].&[Seattle]&[WA]
} ON 1
, {[Measures].[Internet Sales Amount], [Measures].[Reseller Sales Amount]}
ON 0
FROM ( SELECT [Customer].[State-Province].&[WA]&[US] ON 0
        FROM [Adventure Works]
)

```

Returns the following values:

[Expand table](#)

	Internet Sales Amount	Reseller Sales Amount
All Customers	\$2,467,248.34	\$80,450,596.98
United States	\$2,467,248.34	\$80,450,596.98
Washington	\$2,467,248.34	\$80,450,596.98
Seattle	\$75,164.86	\$80,450,596.98

The results above show that only ascendants and descendants of Washington State are part of the subspace where the outer select statement was evaluated; Oregon and Portland have been removed from the subcube because Oregon and all the other sibling states were not mentioned in the subselect when Washington was mentioned.

The All member was adjusted to reflect the filtering on Washington; not only was adjusted in the [Customer Geography] dimension but in all other dimensions that crossed with [Customer

Geography]. All dimensions that do not cross with [Customer Geography] remain in the subcube unaltered.

The following two MDX statements illustrate how the All member in other dimensions is adjusted to meet the filtering effect of the subselect. The first query displays the unaltered results and the second shows the impact of the filtering:

```
SELECT { [Customer].[Customer Geography].[All Customers]
    , [Customer].[Customer Geography].[Country].&[United States]
    , [Customer].[Customer Geography].[State-Province].&[OR]&[US]
    , [Customer].[Customer Geography].[City].&[Portland]&[OR]
    , [Customer].[Customer Geography].[State-Province].&[WA]&[US]
    , [Customer].[Customer Geography].[City].&[Seattle]&[WA]
} ON 1
, [Product].[Product Line].MEMBERS ON 0
FROM [Adventure Works]
WHERE [Measures].[Internet Sales Amount]
```

[Expand table](#)

	All Products	Accessory	Components	Mountain	Road	Touring
All Customers	\$29,358,677.22	\$604,053.30	(null)	\$10,251,183.52	\$14,624,108.58	\$3,879,331.82
United States	\$9,389,789.51	\$217,168.79	(null)	\$3,547,956.78	\$4,322,438.41	\$1,302,225.54
Oregon	\$1,170,991.54	\$30,513.17	(null)	\$443,607.98	\$565,372.10	\$131,498.29
Portland	\$110,649.54	\$2,834.17	(null)	\$47,099.91	\$53,917.17	\$6,798.29
Washington	\$2,467,248.34	\$62,662.92	(null)	\$945,219.38	\$1,155,880.07	\$303,485.97
Seattle	\$75,164.86	\$2,695.74	(null)	\$19,914.53	\$44,820.06	\$7,734.54

```
SELECT { [Customer].[Customer Geography].[All Customers]
    , [Customer].[Customer Geography].[Country].&[United States]
    , [Customer].[Customer Geography].[State-Province].&[OR]&[US]
    , [Customer].[Customer Geography].[City].&[Portland]&[OR]
    , [Customer].[Customer Geography].[State-Province].&[WA]&[US]
    , [Customer].[Customer Geography].[City].&[Seattle]&[WA]
} ON 1
, [Product].[Product Line].MEMBERS ON 0
FROM ( SELECT [Customer].[State-Province].&[WA]&[US] ON 0
        FROM [Adventure Works]
    )
WHERE [Measures].[Internet Sales Amount]
```

[Expand table](#)

	All Products	Accessory	Components	Mountain	Road	Touring
All Customers	\$2,467,248.34	\$62,662.92	(null)	\$945,219.38	\$1,155,880.07	\$303,485.97
United States	\$2,467,248.34	\$62,662.92	(null)	\$945,219.38	\$1,155,880.07	\$303,485.97
Washington	\$2,467,248.34	\$62,662.92	(null)	\$945,219.38	\$1,155,880.07	\$303,485.97
Seattle	\$75,164.86	\$2,695.74	(null)	\$19,914.53	\$44,820.06	\$7,734.54

The above results show that All Products values have been adjusted to only values from Washington State, as expected.

Subselects can be nested with no limit to how deep you can nest subselects, except available memory. The inner most subselect defines the starting subspace over which filtering is applied and passed onto the next outer select. An important thing to notice is the fact that nesting is not a commutative operation; so the order in which the nesting is set my produce different results. The following examples should show the difference when choosing a nesting order.

```
SELECT [Sales Territory].[Sales Territory Region].MEMBERS on 0
      , [Product].[Product].MEMBERS on 1
  FROM (SELECT TOPCOUNT( [Product].[Product].CHILDREN, 5, [Measures].[Sales
Amount]) ON 0
        FROM (SELECT TOPCOUNT( [Sales Territory].[Sales Territory
Region].CHILDREN, 5, [Measures].[Sales Amount]) ON 0
              FROM [Adventure Works]
            )
      )
 WHERE [Measures].[Sales Amount]
```

Returned the following results.

[Expand table](#)

	All Sales Territories	Australia	Canada	Central	Northwest	Southwest
All Products	\$7,591,495.49	\$1,281,059.99	\$1,547,298.12	\$600,205.79	\$1,924,763.50	\$2,238,168.08
Mountain- 200 Silver, 38	\$1,449,576.15	\$248,702.93	\$275,052.45	\$141,103.65	\$349,487.01	\$435,230.12

	All Sales Territories	Australia	Canada	Central	Northwest	Southwest
Mountain-200 Black, 38	\$1,722,896.50	\$218,024.05	\$418,726.43	\$123,929.46	\$486,694.63	\$475,521.93
Mountain-200 Black, 42	\$1,573,655.14	\$239,137.96	\$319,921.61	\$130,102.75	\$420,445.84	\$464,046.98
Mountain-200 Black, 46	\$1,420,500.58	\$192,320.16	\$230,875.99	\$117,044.49	\$424,813.66	\$455,446.27
Road-150 Red, 56	\$1,424,867.11	\$382,874.89	\$302,721.64	\$88,025.44	\$243,322.36	\$407,922.78

```

SELECT [Sales Territory].[Sales Territory Region].MEMBERS on 0
    , [Product].[Product].MEMBERS on 1
    FROM (SELECT TOPCOUNT( [Sales Territory].[Sales Territory Region].CHILDREN, 5,
[Measures].[Sales Amount]) ON 0
        FROM (SELECT TOPCOUNT( [Product].[Product].CHILDREN, 5, [Measures].
[Sales Amount]) on 0
            FROM [Adventure Works]
        )
    )
WHERE [Measures].[Sales Amount]

```

Returned the following results.

[Expand table](#)

	All Sales Territories	Australia	Canada	Northwest	Southwest	United Kingdom
All Products	\$7,938,218.56	\$1,096,312.24	\$1,474,255.49	\$2,042,674.72	\$2,238,099.55	\$1,086,876.56
Mountain-200 Silver, 38	\$1,520,958.53	\$248,702.93	\$275,052.45	\$349,487.01	\$435,230.12	\$212,486.03
Mountain-200 Silver, 42	\$1,392,237.14	\$198,127.15	\$229,679.01	\$361,233.58	\$407,854.24	\$195,343.16
Mountain-200 Black, 38	\$1,861,703.23	\$218,024.05	\$418,726.43	\$486,694.63	\$475,521.93	\$262,736.19

All Sales Territories	Australia	Canada	Northwest	Southwest	United Kingdom	
Mountain-200 Black, 42	\$1,702,427.25	\$239,137.96	\$319,921.61	\$420,445.84	\$464,046.98	\$258,874.87
Mountain-200 Black, 46	\$1,460,892.41	\$192,320.16	\$230,875.99	\$424,813.66	\$455,446.27	\$157,436.31

As you can see there are differences in the results between both sets. The first query answered the question of which are the best selling products in the top 5 selling regions, the second query answered the question of where are the largest sales of the top 5 selling products.

Remarks

Subselects have the following restrictions and limitations:

- The WHERE clause does not filter the subspace.
- The WHERE clause changes the default member in the sub cube only.
- The NON EMPTY clause is not allowed in an axis clause; use a [NonEmpty \(MDX\)](#) function expression instead.
- The HAVING clause is not allowed in an axis clause; use a [Filter \(MDX\)](#) function expression instead.
- By default calculated members are not allowed in subselects; however, this restriction can be changed, in a per session basis, by assigning a value to the **SubQueries** connection string property in [ConnectionString](#) or **DBPROP_MSMD_SUBQUERIES** property in [Supported XMLA Properties \(XMLA\)](#). See [Calculated Members in Subselects and Subcubes](#) for a detailed explanation of the behavior of calculated members depending on the values of **SubQueries** or **DBPROP_MSMD_SUBQUERIES**.

Tuples

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A tuple uniquely identifies a slice of data from a cube. The tuple is formed by a combination of dimension members, as long as there are no two or more members that belong to the same hierarchy.

Implicit or default attribute members in a tuple

When defining a tuple in an MDX query or expression, you do not need to explicitly include the attribute member from every attribute hierarchy. If a member from an attribute hierarchy is not explicitly included in a query or an expression, the default member for that attribute hierarchy is the attribute member implicitly included in the tuple. Unless otherwise explicitly defined in a cube, the default member for every attribute hierarchy is the (All) member, if an (All) member exists. If an (All) member does not exist within an attribute hierarchy, the default member is a member of the attribute hierarchy's top level. The default measure is the first measure specified in the cube, unless a default measure is explicitly defined. For more information, see [Define a Default Member](#) and [DefaultMember \(MDX\)](#).

For example, the following tuple identifies a single cell in the Adventure Works database by explicitly defining only a single member of the Measures dimension.

```
(Measures.[Reseller Sales Amount])
```

The previous example uniquely identifies the cell consisting of the Reseller Sales Amount member from the Measures dimension and the default member from every attribute hierarchy in the cube. The default member is the (All) member for every attribute hierarchy other than the Destination Currency attribute hierarchy. The default member for the Destination Currency hierarchy is the US Dollar member (this default member is defined in the MDX script for the Adventure Works cube).

 **Important**

The member of an attribute hierarchy in a tuple is also affected by relationships that are defined between attributes within a dimension.

The following query returns the value for the cell referenced by the tuple specified in the previous example, (\$80,450.596.98).

```
SELECT  
Measures.[Reseller Sales Amount] ON COLUMNS  
FROM [Adventure Works]
```

ⓘ Note

When you specify an axis for a set (in this case composed of a single tuple) in a query, you must begin by specifying a set for the column axis before specifying a set for the row axis. The column axis can also be referred to as *axis(0)* or simply *0*. For more information about MDX queries, see [The Basic MDX Query \(MDX\)](#).

Tuples as values or member references

You can use a tuple in a query to return the value in the cell that is referenced by the tuple, as in the previous example. Or you can use a tuple in an expression to explicitly refer to the members specified in the tuple. The query or the expression can utilize functions that either return or consume tuples. A tuple can be used to either refer to the value of the cell that the tuple specifies, or to specify a combination of members when utilized in a function.

Tuple dimensionality

The *dimensionality* of a tuple refers to the sequence or order of the members in the tuple. Since the implicit members always occur in the same order, dimensionality is most often thought of in terms of the explicitly defined members of the tuple. The ordering of the members of the tuple is important when you define a set of tuples. The following example includes two members in a tuple on the column axis.

```
SELECT  
([Measures].[Reseller Sales Amount],[Date].[Calendar Year].[CY 2004]) ON
```

```
COLUMNS  
FROM [Adventure Works]
```

ⓘ Note

When you explicitly specify a member in a tuple from more than one dimension, you must include the entire tuple in parentheses. When only specifying a single member in a tuple, parentheses are optional.

The tuple in the query in the previous example specifies the return of the cube cell at the intersection of the Reseller Sales Amount Measure of the Measures dimension and the CY 2004 member of the Calendar Year attribute hierarchy in the Date dimension.

ⓘ Note

An attribute member can be referred by either its member name or its member key. In the previous example, you could replace the reference to [CY 2004] with &[2004].

Visual Totals and Non Visual Totals

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Visual Totals are totals at the end of a column or row that add up all of the items visible in the column or row. This is the default behavior for most tables when displayed. However, there are times when the user wants to display only certain columns in a table but keep the totals for the entire row, including those that are not displayed. These are called **Non Visual Totals**, because the total comes from both the visible and non-visible values.

The following scenario demonstrates the behavior of Non Visual totals. The first step shows the default behavior of Visual Totals.

The following example is a query of [Adventure Works] to obtain [Reseller Sales Amount] figures in a table where the product categories are the columns and the reseller business types are the rows. Note that totals are given for both products and resellers when the following SELECT statement is issued:

```
select [Category].members on 0,  
[Business Type].members on 1  
from [Adventure Works]  
where [Measures].[Reseller Sales Amount]
```

Produces the following results:

Expand table

	All Products	Accessories	Bikes	Clothing	Components
All Resellers	\$80,450,596.98	\$571,297.93	\$66,302,381.56	\$1,777,840.84	\$11,799,076.66
Specialty Bike Shop	\$6,756,166.18	\$65,125.48	\$6,080,117.73	\$252,933.91	\$357,989.07
Value Added Reseller	\$34,967,517.33	\$175,002.81	\$30,892,354.33	\$592,385.71	\$3,307,774.48
Warehouse	\$38,726,913.48	\$331,169.64	\$29,329,909.50	\$932,521.23	\$8,133,313.11

Non-Visual on rows and columns

To produce a table with data only for the Accessories and Clothing products, the Value Added Reseller and Warehouse resellers, yet keeping the overall totals could be written as follows using NON VISUAL:

```
select [Category].members on 0,  
[Business Type].members on 1  
  
from NON VISUAL (Select {[Category].Accessories, [Category].Clothing} on 0,  
{[Business Type].[Value Added Reseller], [Business Type].[Warehouse]} on 1  
  
from [Adventure Works])  
  
where [Measures].[Reseller Sales Amount]
```

Produces the following results:

[\[\] Expand table](#)

	All Products	Accessories	Clothing
All Resellers	\$80,450,596.98	\$571,297.93	\$1,777,840.84
Value Added Reseller	\$34,967,517.33	\$175,002.81	\$592,385.71
Warehouse	\$38,726,913.48	\$331,169.64	\$932,521.23

Non-Visual on rows

To produce a table that visually totals the columns but for row totals brings the true total of all [Category], the following query should be issued:

```
select [Category].members on 0,  
[Business Type].members on 1  
  
from NON VISUAL (Select {[Category].Accessories, [Category].Clothing} on 0  
from ( Select {[Business Type].[Value Added Reseller], [Business Type].[Warehouse]}  
on 0  
  
from [Adventure Works])
```

)

```
where [Measures].[Reseller Sales Amount]
```

Note how NON VISUAL is only applied to [Category].

The above query produces the following results:

[Expand table](#)

	All Products	Accessories	Clothing
All Resellers	\$73,694,430.80	\$506,172.45	\$1,524,906.93
Value Added Reseller	\$34,967,517.33	\$175,002.81	\$592,385.71
Warehouse	\$38,726,913.48	\$331,169.64	\$932,521.23

When compared with the previous results, you can observe that the [All Resellers] row now adds up to the displayed values for [Value Added Reseller] and [Warehouse] but that the [All Products] column shows the total value for all products, including those not displayed.

Working with Members, Tuples, and Sets (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

MDX provides numerous functions that return one or more members, tuples, or sets; or that act upon a member, tuple, or set.

Member Functions

MDX provides several functions for retrieving members from other MDX entities, such as from dimensions, levels, sets, or tuples. For example, the [FirstChild](#) function is a function that acts upon a member and returns a member.

To obtain the first child member of the Time dimension, you can explicitly state the member, as in the following example.

```
SELECT [Date].[Calendar Year].[CY 2001] on 0  
FROM [Adventure Works]
```

You can also use the [FirstChild](#) function to return the same member, as in the following example.

```
SELECT [Date].[Calendar Year].FirstChild on 0  
FROM [Adventure Works]
```

For more information about MDX member functions, see [MDX Function Reference \(MDX\)](#).

Tuple Functions

MDX provides several functions that return tuples, and they can be used anywhere that a tuple is accepted. For example, the [Item \(Tuple\) \(MDX\)](#) function can be used to extract

the first tuple from set, which is very useful when you know that a set is composed of a single tuple and you want to supply that tuple to a function that requires a tuple.

The following example returns the first tuple from within the set of tuples on the column axis.

```
SELECT {  
    ([Measures].[Reseller Sales Amount]  
     ,[Date].[Calendar Year].[CY 2003]  
    )  
, ([Measures].[Reseller Sales Amount]  
     ,[Date].[Calendar Year].[CY 2004]  
    )  
}.Item(0)  
ON COLUMNS  
FROM [Adventure Works]
```

For more information about tuple functions, see [MDX Function Reference \(MDX\)](#).

Set Functions

MDX provides several functions that return sets. Explicitly typing tuples and enclosing them in braces is not the only way to retrieve a set. For more information about the members function to return a set, see [Key Concepts in MDX \(Analysis Services\)](#). There are many additional set functions.

The colon operator lets you use the natural order of members to create a set. For example, the set shown in the following example contains tuples for the 1st through the 4th quarter of calendar year 2002.

```
SELECT  
    {[Calendar Quarter].[Q1 CY 2002]:[Calendar Quarter].[Q4 CY 2002]}  
ON 0  
FROM [Adventure Works]
```

If you do not use the colon operator to create the set, you can create the same set of members by specifying the tuples in the following example.

```
SELECT {  
    [Calendar Quarter].[Q1 CY 2002],
```

```
[Calendar Quarter].[Q2 CY 2002],  
[Calendar Quarter].[Q3 CY 2002],  
[Calendar Quarter].[Q4 CY 2002]  
} ON 0  
FROM [Adventure Works]
```

The colon operator is an inclusive function. The members on both sides of the colon operator are included in the resulting set.

For more information about set functions, see [MDX Function Reference \(MDX\)](#).

Array Functions

An array function acts upon a set and returns an array. For more information about array functions, see [MDX Function Reference \(MDX\)](#).

Hierarchy Functions

A hierarchy function returns a hierarchy by acting upon a member, level, hierarchy, or string. For more information about hierarchy functions, see [MDX Function Reference \(MDX\)](#).

Level Functions

A level function returns a level by acting upon a member, level, or string. For more information about level functions, see [MDX Function Reference \(MDX\)](#).

Logical Functions

A logical function acts upon a MDX expression to return information about the tuples, members, or sets in the expression. For example, the [IsEmpty \(MDX\)](#) function evaluates whether an expression has returned an empty cell value. For more information about logical functions, see [MDX Function Reference \(MDX\)](#).

Numeric Functions

A numeric function acts upon a MDX expression to return a scalar value. For example, the [Aggregate \(MDX\)](#) function returns a scalar value calculated by aggregating

measures over the tuples in a specified set. For more information about numeric functions, see [MDX Function Reference \(MDX\)](#).

String Functions

A string function acts upon a MDX expression to return a string. For example, the [UniqueName \(MDX\)](#) function returns a string value containing the unique name of a dimension, hierarchy, level, or member. For more information about string functions, see [MDX Function Reference \(MDX\)](#).

MDX Query Fundamentals (Analysis Services)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Multidimensional Expressions (MDX) lets you query multidimensional objects, such as cubes, and return multidimensional cellsets that contain the cube's data. This topic and its subtopics provide an overview of MDX queries.

The following topics describe MDX queries and the cellsets they produce, and provide more detailed information about basic MDX syntax.

In This Section

 Expand table

Topic	Description
The Basic MDX Query (MDX)	Provides basic syntax information for the MDX SELECT statement.
Restricting the Query with Query and Slicer Axis (MDX)	Describes what query and slicer axes are and how to specify them.
Establishing Cube Context in a Query (MDX)	Provides a description of the purpose of the FROM clause in an MDX SELECT statement.
Building Named Sets in MDX (MDX)	Describes the purpose of named sets in MDX, and the techniques needed to create and use them in MDX queries.

MDX Query - The Basic Query

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The basic Multidimensional Expressions (MDX) query is the SELECT statement—the most frequently used query in MDX. By understanding how an MDX SELECT statement must specify a result set, what the syntax of the SELECT statement is, and how to create a simple query using the SELECT statement, you will have a solid understanding of how to use MDX to query multidimensional data.

Specifying a Result Set

In MDX, the SELECT statement specifies a result set that contains a subset of multidimensional data that has been returned from a cube. To specify a result set, an MDX query must contain the following information:

- The number of axes that you want the result set to contain. You can specify up to 128 axes in an MDX query.
- The set of members or tuples to include on each axis of the MDX query.
- The name of the cube that sets the context of the MDX query.
- The set of members or tuples to include on the slicer axis. For more information about slicer and query axes, see [Restricting the Query with Query and Slicer Axes \(MDX\)](#).

To identify the query axes, the cube that will be queried, and the slicer axis, the MDX SELECT statement uses the following clauses:

- A SELECT clause that determines the query axes of an MDX SELECT statement. For more information about the construction of query axes in a SELECT clause, see [Specifying the Contents of a Query Axis \(MDX\)](#).
- A FROM clause that determines which cube will be queried. For more information about the FROM clause, see [SELECT Statement \(MDX\)](#).
- An optional WHERE clause that determines which members or tuples to use on the slicer axis to restrict the data returned. For more information about the construction of a slicer axis in a WHERE clause, see [Specifying the Contents of a Slicer Axis \(MDX\)](#).

Note

For more detailed information about the various clauses of the SELECT statement, see [SELECT Statement \(MDX\)](#).

SELECT Statement Syntax

The following syntax shows a basic SELECT statement that includes the use of the SELECT, FROM, and WHERE clauses:

```
[ WITH <SELECT WITH clause> [ , <SELECT WITH clause> ... ] ]
SELECT [ * | ( <SELECT query axis clause>
    [ , <SELECT query axis clause> ... ] ) ]
FROM <SELECT subcube clause>
[ <SELECT slicer axis clause> ]
[ <SELECT cell property list clause> ]
```

The MDX SELECT statement supports optional syntax, such as the WITH keyword, the use of MDX functions to create calculated members for inclusion in an axis or slicer axis, and the ability to return the values of specific cell properties as part of the query. For more information about the MDX SELECT statement, see [SELECT Statement \(MDX\)](#).

Comparing the Syntax of the MDX SELECT Statement to SQL

The syntax format for the MDX SELECT statement is similar to that of SQL syntax. However, there are several fundamental differences:

- MDX syntax distinguishes sets by surrounding tuples or members with braces (the { and } characters.) For more information about member, tuple, and set syntax, see [Working with Members, Tuples, and Sets \(MDX\)](#).
- MDX queries can have 0, 1, 2 or up to 128 query axes in the SELECT statement. Each axis behaves in exactly the same way, unlike SQL where there are significant differences between how the rows and the columns of a query behave.
- As with an SQL query, the FROM clause names the source of the data for the MDX query. However, the MDX FROM clause is restricted to a single cube. Information from other cubes can be retrieved on a value-by-value basis by using the LookupCube function.

- The WHERE clause describes the slicer axis in an MDX query. It acts as something like an invisible, extra axis in the query, slicing the values that appear in the cells in the result set; unlike the SQL WHERE clause it does not directly affect what appears on the rows axis of the query. The functionality of the SQL WHERE clause is available through other MDX functions such as the FILTER function.

SELECT Statement Example

The following example shows a basic MDX query that uses the SELECT statement. This query returns a result set that contains the 2002 and 2003 sales and tax amounts for the Southwest sales territories.

```

SELECT
    { [Measures].[Sales Amount],
      [Measures].[Tax Amount] } ON COLUMNS,
    { [Date].[Fiscal].[Fiscal Year].&[2002],
      [Date].[Fiscal].[Fiscal Year].&[2003] } ON ROWS
  FROM [Adventure Works]
 WHERE ( [Sales Territory].[Southwest] )

```

In this example, the query defines the following result set information:

- The SELECT clause sets the query axes as the Sales Amount and Tax Amount members of the Measures dimension, and the 2002 and 2003 members of the Date dimension.
- The FROM clause indicates that the data source is the Adventure Works cube.
- The WHERE clause defines the slicer axis as the Southwest member of the Sales Territory dimension.

Notice that the query example also uses the COLUMNS and ROWS axis aliases. The ordinal positions for these axes could also have been used. The following example shows how the MDX query could have been written to use the ordinal position of each axis:

```

SELECT
    { [Measures].[Sales Amount],
      [Measures].[Tax Amount] } ON 0,
    { [Date].[Fiscal].[Fiscal Year].&[2002],
      [Date].[Fiscal].[Fiscal Year].&[2003] } ON 1

```

```
FROM [Adventure Works]
WHERE ( [Sales Territory].[Southwest] )
```

For more detailed examples, see [Specifying the Contents of a Query Axis \(MDX\)](#) and [Specifying the Contents of a Slicer Axis \(MDX\)](#).

MDX Query - EXISTING Keyword

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Forces a specified set to be evaluated within the current context.

Syntax

```
Existing Set_Expression
```

Arguments

Set_Expression

A valid Multidimensional Expressions (MDX) set expression.

Remarks

By default, sets are evaluated within the context of the cube that contains the members of the set. The **Existing** keyword forces a specified set to be evaluated within the current context instead.

Example

The following example returns the count of the resellers whose sales have declined over the previous time period, based on user-selected State-Province member values evaluated using the **Aggregate** function. The [Hierarchize \(MDX\)](#) and [DrilldownLevel \(MDX\)](#) functions are used to return values for declining sales for product categories in the Product dimension. The **Existing** keyword forces the set in the **Filter** function to be evaluated in the current context - that is, for the Washington and Oregon members of the State-Province attribute hierarchy.

```

WITH MEMBER Measures.[Declining Reseller Sales] AS
  Count
    (Filter
      (Existing
        (Reseller.Reseller.Reseller)
        , [Measures].[Reseller Sales Amount] <
          ([Measures].[Reseller Sales Amount]
            ,[Date].Calendar.PrevMember
          )
        )
      )
    )
MEMBER [Geography].[State-Province].x AS
  Aggregate
    ( {[Geography].[State-Province].&[WA]&[US]
      , [Geography].[State-Province].&[OR]&[US] }
    )
SELECT NON EMPTY HIERARCHIZE
  (AddCalculatedMembers
    (
      {DrillDownLevel
        ({ {[Product].[All Products]}}
        )
      }
    )
  ) DIMENSION PROPERTIES PARENT_UNIQUE_NAME ON COLUMNS
FROM [Adventure Works]
WHERE
  ( [Geography].[State-Province].x
    , [Date].[Calendar].[Calendar Quarter].&[2003]&[4]
    ,[Measures].[Declining Reseller Sales]
  )

```

MDX Query and Slicer Axes - Restricting the Query

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

When formulating a Multidimensional Expressions (MDX) SELECT statement, an application typically examines a cube and divides the set of hierarchies into two subsets:

- **Query axes**-the set of hierarchies from which data is retrieved for multiple members. For more information about query axes, see [Specifying the Contents of a Query Axis \(MDX\)](#).
- **Slicer axis**-the set of hierarchies from which data is retrieved for a single member. For more information about the slicer axis, see [Specifying the Contents of a Slicer Axis \(MDX\)](#).

Because query and slicer axes can be constructed from multiple hierarchies of the cube to be queried, these terms are used to differentiate the hierarchies used by the cube that is to be queried from the hierarchies created in the cube returned by an MDX query.

To see a simple example using query and slicer axes, see [Using Query and Slicer Axes in a Simple Example \(MDX\)](#).

MDX Query and Slicer Axes - Specify the Contents of a Query Axis

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Query axes specify the edges of a cellset returned by a Multidimensional Expressions (MDX) SELECT statement. Specifying the edges of a cellset lets you restrict the returned data that is visible to the client.

To specify query axes, you use the `<SELECT query axis clause>` to assign a set to a particular query axis. Each `<SELECT query axis clause>` value defines one query axis. The number of axes in the dataset is equal to the number of `<SELECT query axis clause>` values in the SELECT statement.

Query Axis Syntax

The following syntax shows the syntax for the `<SELECT query axis clause>`:

```
<SELECT query axis clause> ::=  
    [ NON EMPTY ] Set_Expression [ <SELECT dimension property list clause> ]  
    [<HAVING clause>]  
    ON {  
        Integer_Expression |  
        AXIS( Integer_Expression ) |  
        {COLUMNS | ROWS | PAGES | SECTIONS | CHAPTERS}  
    }
```

Each query axis has a number: zero (0) for the x-axis, 1 for the y-axis, 2 for the z-axis, and so on. In the syntax for the `<SELECT query axis clause>`, the `Integer_Expression` value specifies the axis number. An MDX query can support up to 128 specified axes, but very few MDX queries will use more than 5 axes. For the first 5 axes, the aliases COLUMNS, ROWS, PAGES, SECTIONS, and CHAPTERS can instead be used.

An MDX query cannot skip query axes. That is, a query that includes one or more query axes must not exclude lower-numbered or intermediate axes. For example, a query

cannot have a ROWS axis without a COLUMNS axis, or have COLUMNS and PAGES axes without a ROWS axis.

However, you can specify a SELECT clause without any axes (that is, an empty SELECT clause). In this case, all dimensions are slicer dimensions, and the MDX query selects one cell.

In the query axis syntax previously shown, each `Set_Expression` value specifies the set that defines the contents of the query axis. For more information about sets, see [Working with Members, Tuples, and Sets \(MDX\)](#).

Examples

The following simple SELECT statement returns the measure Internet Sales Amount on the Columns axis, and uses the MDX MEMBERS function to return all the members from the Calendar hierarchy on the Date dimension on the Rows axis:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
{[Date].[Calendar].MEMBERS} ON ROWS  
FROM [Adventure Works]
```

The two following queries return exactly the same results but demonstrate the use of axis numbers rather than aliases:

```
SELECT {[Measures].[Internet Sales Amount]} ON 0,  
{[Date].[Calendar].MEMBERS} ON 1  
FROM [Adventure Works]
```

```
SELECT {[Measures].[Internet Sales Amount]} ON AXIS(0),  
{[Date].[Calendar].MEMBERS} ON AXIS(1)  
FROM [Adventure Works]
```

The NON EMPTY keyword, used before the set definition, is an easy way to remove all empty tuples from an axis. For example, in the examples we've seen so far there is no data in the cube from August 2004 onwards. To remove all rows from the cellset that have no data in any column, simply add NON EMPTY before the set on the Rows axis definition as follows:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
NON EMPTY  
{[Date].[Calendar].MEMBERS} ON ROWS  
FROM [Adventure Works]
```

NON EMPTY can be used on all axes in a query. Compare the results of the following two queries, the first of which does not use NON EMPTY and the second of which does on both axes:

```
SELECT {[Measures].[Internet Sales Amount]}  
* [Promotion].[Promotion].[Promotion].MEMBERS  
ON COLUMNS,  
{[Date].[Calendar].[Calendar Year].MEMBERS} ON ROWS  
FROM [Adventure Works]  
WHERE([Product].[Subcategory].&[19])  
  
SELECT NON EMPTY {[Measures].[Internet Sales Amount]}  
* [Promotion].[Promotion].[Promotion].MEMBERS  
ON COLUMNS,  
NON EMPTY  
{[Date].[Calendar].[Calendar Year].MEMBERS} ON ROWS  
FROM [Adventure Works]  
WHERE([Product].[Subcategory].&[19])
```

The HAVING clause can be used to filter the contents of an axis based on a specific criteria; it is less flexible than other methods that can achieve the same results, such as the FILTER function, but it is simpler to use. Here is an example that returns only those dates where Internet Sales Amount is greater than \$15,000:

```
SELECT {[Measures].[Internet Sales Amount]}  
ON COLUMNS,  
NON EMPTY  
{[Date].[Calendar].[Date].MEMBERS}  
HAVING [Measures].[Internet Sales Amount]>15000  
ON ROWS  
FROM [Adventure Works]
```

MDX Query and Slicer Axes - Specify the Contents of a Slicer Axis

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

The slicer axis filters the data returned by the Multidimensional Expressions (MDX) SELECT statement, restricting the returned data so that only data intersecting with the specified members will be returned. It can be thought of as an invisible extra axis in a query. The slicer axis is defined in the WHERE clause of the SELECT statement in MDX.

Slicer Axis Syntax

To explicitly specify a slicer axis, you use the `<SELECT slicer axis clause>` in MDX, as described in the following syntax:

```
<SELECT slicer axis clause> ::= WHERE Set_Expression
```

In the slicer axis syntax shown, `Set_Expression` can take either a tuple expression, which is treated as a set for the purposes of evaluating the clause, or a set expression. If a set expression is specified, MDX will try to evaluate the set, aggregating the result cells in every tuple along the set. In other words, MDX will try to use the [Aggregate](#) function on the set, aggregating each measure by its associated aggregation function. Also, if the set expression cannot be expressed as a crossjoin of attribute hierarchy members, MDX treats cells that fall outside of the set expression for the slicer as null for evaluation purposes.

Important

Unlike the WHERE clause in SQL, the WHERE clause of an MDX SELECT statement never directly filters what is returned on the Rows axis of a query. To filter what appears on the Rows or Columns axis of a query, you can use a variety of MDX functions, for example FILTER, NONEMPTY and TOPCOUNT.

Implicit Slicer Axis

If a member from a hierarchy within the cube is not explicitly included in a query axis, the default member from that hierarchy is implicitly included in the slicer axis. For more information about default members, see [Define a Default Member](#).

Examples

The following query does not include a WHERE clause, and returns the value of the Internet Sales Amount measure for all Calendar Years:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
[Date].[Calendar Year].MEMBERS ON ROWS  
FROM [Adventure Works]
```

Adding a WHERE clause, as follows:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
[Date].[Calendar Year].MEMBERS ON ROWS  
FROM [Adventure Works]  
WHERE([Customer].[Customer Geography].[Country].&[United States])
```

does not change what is returned on Rows or Columns in the query; it changes the values returned for each cell. In this example, the query is sliced so that it returns the value of Internet Sales Amount for all Calendar Years but only for Customers who live in the United States. Multiple members from different hierarchies can be added to the WHERE clause. The following query shows the value of Internet Sales Amount for all Calendar Years for Customers who live in the United States and who bought Products in the Category Bikes:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
[Date].[Calendar Year].MEMBERS ON ROWS  
FROM [Adventure Works]  
WHERE([Customer].[Customer Geography].[Country].&[United States], [Product].[Category].&[1])
```

If you want to use multiple members from the same hierarchy, you need to include a set in the WHERE clause. For example, the following query shows the value of Internet Sales

Amount for all Calendar Years for Customers who bought Products in the Category Bikes and live in either the United States or the United Kingdom:

```
SELECT {[Measures].[Internet Sales Amount]} ON COLUMNS,  
[Date].[Calendar Year].MEMBERS ON ROWS  
FROM [Adventure Works]  
WHERE(  
{[Customer].[Customer Geography].[Country].&[United States]  
, [Customer].[Customer Geography].[Country].&[United Kingdom]})  
, [Product].[Category].&[1])
```

As mentioned above, using a set in the WHERE clause will implicitly aggregate values for all members in the set. In this case, the query shows aggregated values for the United States and the United Kingdom in each cell.

MDX Query and Slicer Axes - Using Axes in a Simple Example

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

The simple example presented in this topic illustrates the basics of specifying and using query and slicer axes.

The Cube

A cube, named TestCube, has two simple dimensions named Route and Time. Each dimension has only one user hierarchy, named Route and Time respectively. Because the measures of the cube are part of the Measures dimension, this cube has three dimensions in all.

The Query

The query is to provide a matrix in which the Packages measure can be compared across routes and times.

In the following MDX query example, the Route and Time hierarchies are the query axes, and the Measures dimension is the slicer axis. The **Members** function indicates that MDX will use the members of the hierarchy or level to construct a set. The use of the **Members** function means that you do not have to explicitly state each member of a specific hierarchy or level in an MDX query.

```
SELECT
    { Route.nonground.Members } ON COLUMNS,
    { Time.[1st half].Members } ON ROWS
FROM TestCube
WHERE ( [Measures].[Packages] )
```

The Results

The result is a grid that identifies the value of the Packages measure at each intersection of the COLUMNS and ROWS axis dimensions. The following table shows how this grid

would look.

 Expand table

	air	sea
1st quarter	60	50
2nd quarter	45	45

Establishing Cube Context in a Query (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Every MDX query runs within a specified cube context. This context defines the members that are evaluated by the expressions within the query.

In the SELECT statement, the FROM clause determines the cube context. This context can be the whole cube or just a subcube from that cube. Having specified cube context through the FROM clause, you can use additional functions to expand or restrict that context.

Note

The SCOPE and CALCULATE statements also let you manage cube context from within an MDX script. For more information, see [MDX Scripting Fundamentals \(Analysis Services\)](#).

FROM Clause Syntax

The following syntax describes the FROM clause:

```
<SELECT subcube clause> ::=  
    Cube_Identifier |  
    (SELECT [  
        * |  
        ( <SELECT query axis clause> [ , <SELECT query axis clause> ... ] ) ]  
    FROM <SELECT subcube clause> <SELECT slicer axis clause> )
```

In this syntax, notice that it is the `<SELECT subcube clause>` clause that describes the cube or subcube on which the SELECT statement is executed.

A simple example of a FROM clause would be one that runs against the entire Adventure Works sample cube. Such a FROM clause would have the following format:

```
FROM [Adventure Works]
```

For more information about the FROM clause in the MDX SELECT statement, see [SELECT Statement \(MDX\)](#).

Refining the Context

Although the FROM clause specifies the cube context as within a single cube, this does not have to limit you from working with data from more than one cube at a time.

You can use the MDX [LookupCube](#) function to retrieve data from cubes outside the cube context. Additionally, functions such as the [Filter](#) function, are available that allow temporary restriction of the context while evaluating the query.

Building Subcubes in MDX (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A subcube is a subset of a cube on representing a filtered view of the underlying data. By limiting the cube to a subcube, you can improve query performance.

To define a subcube, you use the [CREATE SUBCUBE](#) statement, as described in this topic.

CREATE SUBCUBE Syntax

Use the following syntax to create a subcube:

```
CREATE SUBCUBE Subcube_Identifier AS Subcube_Expression
```

The CREATE SUBCUBE syntax is fairly simple. The *Subcube_Identifier* parameter identifies the cube on which the subcube will be based. The *Subcube_Expression* parameter selects the part of the cube that will become the subcube

After you create a subcube, that subcube becomes the context for all MDX queries until either the session closes or you run the [DROP SUBCUBE](#) statement.

What a Subcube Contains

Although the CREATE SUBCUBE statement is fairly simple to use, the statement itself does not explicitly show all the members that become part of a subcube. In defining a subcube, the following rules apply:

- If you include the (All) member of a hierarchy, you include every member of that hierarchy.
- If you include any member, you include that member's ascendants and descendants.
- If you include every member from a level, you include all members from the hierarchy. Members from other hierarchies will be excluded if those members do not exist with members from the level (for example, an unbalanced hierarchy such as a city that does not contain customers).

- A subcube will always contain every (**All**) member from the cube.

Additionally, aggregate values within the subcube are visually totaled. For example, a subcube contains `USA`, `WA`, and `OR`. The aggregate value for `USA` will be the sum of `{WA,OR}` because `WA` and `OR` are the only states defined by the subcube. All other states will be ignored.

Also, explicit references to cells outside the subcube return cell values that are evaluated in the context of the whole cube. For example, you create a subcube that is limited to the current year. You then use the `ParallelPeriod` function to compare the current year to the previous year. The difference in values will be returned even though the previous year's value lies outside the subcube.

Finally, if the original context is not overwritten, set functions evaluated in a subselect are evaluated in the context of the subselect. If the context is overwritten, set functions are evaluated in the context of the whole cube.

CREATE SUBCUBE Example

The following example creates a subcube that restricts the Budget cube to only accounts 4200 and 4300:

```
CREATE SUBCUBE Budget AS SELECT {[Account].[Account].&[4200], [Account].[Account].&[4300] } ON 0 FROM Budget
```

Having created a subcube for the session, any subsequent queries will be against the subcube, not the whole cube. For example, you run the following query. This query will only return members from accounts 4200 and 4300.

```
SELECT [Account].[Account].Members ON 0, Measures.Members ON 1 FROM Budget
```

MDX Named Sets - Building Named Sets

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

A set expression can be a lengthy and complex declaration, and therefore be difficult to follow or understand. Or, a set expression may be used so frequently that repeatedly defining the set becomes burdensome. To help make working with a lengthy, complex or commonly used expression easier, Multidimensional Expressions (MDX) lets you such an expression as a *named set*.

Basically, a named set is a set expression to which an alias has been assigned. A named set can incorporate any members or functions that can ordinarily be incorporated into a set. Because MDX treats the named set alias as a set expression, you can use that alias anywhere a set expression is accepted.

You can define a named set to have one of the following contexts:

- **Query-scoped** To create a named set that is defined as part of an MDX query, and therefore whose scope is limited to the query, you use the WITH keyword. You can then use the named set within an MDX SELECT statement. Using this approach, the named set created by using the WITH keyword can be changed without disturbing the SELECT statement.

For more information about how to use the WITH keyword to create named sets, see [Creating Query-Scoped Named Sets \(MDX\)](#).

- **Session-scoped** To create a named set whose scope is wider than the context of the query, that is, whose scope is the lifetime of the MDX session, you use the CREATE SET statement. A named set defined by using the CREATE SET statement is available to all MDX queries in that session. The CREATE SET statement makes sense, for example, in a client application that consistently reuses a set in a variety of queries.

For more information about how to use the CREATE SET statement to create named sets in a session, see [Creating Session-Scoped Named Sets \(MDX\)](#).

MDX Named Sets - Creating Query-Scoped Named Sets

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

If a named set is only required for a single Multidimensional Expressions (MDX) query, you can define that named set by using the WITH keyword. A named set that is created by using the WITH keyword no longer exists after the query has finished running.

As discussed in this topic, the syntax of the WITH keyword is quite flexible, even accommodating the use of functions to define the named set.

Note

For more information about named sets, see [Building Named Sets in MDX \(MDX\)](#).

WITH Keyword Syntax

Use the following syntax to add the WITH keyword to a MDX SELECT statement:

```
[ WITH <SELECT WITH clause> [ , <SELECT WITH clause> ... ] ]
SELECT [ * | ( <SELECT query axis clause> [ , <SELECT query axis clause> ...
] ) ]
FROM <SELECT subcube clause>
[ <SELECT slicer axis clause> ]
[ <SELECT cell property list clause> ]

<SELECT WITH clause> ::= 
    ( SET Set_Identifier AS 'Set_Expression' )
```

In the syntax for the WITH keyword, the `Set_Identifier` parameter contains the alias for the named set. The `Set_Expression` parameter contains the set expression to which the named set alias refers.

WITH Keyword Example

The following MDX query examines the unit sales of the various Chardonnay and Chablis wines in **FoodMart 2000**, the sample database for Microsoft SQL Server 2000 Analysis Services. This query, although fairly simple in terms of the result set, is lengthy and unwieldy when you have to maintenance such a query.

```
SELECT
    {[Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Good].[Good Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Pearl].[Pearl Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Portsmouth].[Portsmouth Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Top Measure].[Top Measure Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Walrus].[Walrus Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Good].[Good Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Pearl].[Pearl Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Portsmouth].[Portsmouth Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Top Measure].[Top Measure Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Walrus].[Walrus Chablis Wine]} ON COLUMNS,
    {Measures.[Unit Sales]} ON ROWS
FROM Sales
```

To make the previous MDX query easier to maintain, you can create a named set for the query by using the **WITH** keyword. The following code shows how to use the **WITH** keyword to create a named set, **[ChardonnayChablis]**, and how the named set makes the **SELECT** statement shorter and easier to maintain.

```
WITH SET [ChardonnayChablis] AS
    {[Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Good].[Good Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Pearl].[Pearl Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Portsmouth].[Portsmouth Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Top Measure].[Top Measure Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Walrus].[Walrus Chardonnay], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Good].[Good Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].[Wine].[Pearl].[Pearl Chablis Wine], [Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine]}.
```

```
[Wine].[Portsmouth].[Portsmouth Chablis Wine],  
[Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].  
[Wine].[Top Measure].[Top Measure Chablis Wine],  
[Product].[All Products].[Drink].[Alcoholic Beverages].[Beer and Wine].  
[Wine].[Walrus].[Walrus Chablis Wine]]
```

```
SELECT  
[ChardonnayChablis] ON COLUMNS,  
{Measures.[Unit Sales]} ON ROWS  
FROM Sales
```

Using Functions Together with the WITH Keyword

Although you can explicitly define each member of a named set, this approach can produce a lengthy statement. To make the creation and maintenance of a named set easier, you can use MDX functions to define the members.

For example, the following MDX query example uses the [Filter](#), [CurrentMember](#), and [Name](#) MDX functions and the InStr VBA function to create the `[ChardonnayChablis]` named set. This version of the `[ChardonnayChablis]` named set is the same as the explicitly defined version shown previously in this topic.

```
WITH SET [ChardonnayChablis] AS  
'Filter([Product].Members, (InStr(1, [Product].CurrentMember.Name,  
"chardonnay") <> 0) OR (InStr(1, [Product].CurrentMember.Name, "chablis") <>  
0))'  
  
SELECT  
[ChardonnayChablis] ON COLUMNS,  
{Measures.[Unit Sales]} ON ROWS  
FROM Sales
```

MDX Named Sets - Creating Session-Scope Named Sets

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

To create a named set that is available throughout a Multidimensional Expressions (MDX) session, you use the [CREATE SET](#) statement. A named set that is created by using the CREATE SET statement will not be removed until after the MDX session closes.

As discussed in this topic, the syntax of the WITH keyword is straightforward and easy to use.

Note

For more information about named sets, see [Building Named Sets in MDX \(MDX\)](#).

CREATE SET Syntax

Use the following syntax for the CREATE SET statement:

```
CREATE SESSION SET [CURRENTCUBE. | <cube name>.]<Set Identifier> AS <Set Expression>
```

In the CREATE SET syntax, the `cube name` parameter contains the name of the cube that contains the members for the named set. If the `cube name` parameter is not specified, the current cube will be used as the cube that contains the member for the named set. Also, the `Set_Identifier` parameter contains the alias for the named set, and the `Set_Expression` parameter contains the set expression to which the named set alias will refer.

CREATE SET Example

The following example uses the CREATE SET statement to create the `SetCities_2_3` named set based on the Store cube. The members of the `SetCities_2_3` named set are

the stores within City 2 and City 3.

```
create Session set [Store].[SetCities_2_3] as
{[Data Stores].[ByLocation].[State].&[CA].&[City 02],
[Data Stores].[ByLocation].[State].&[NH].&[City 03]}
```

By using the CREATE SET statement to define the `SetCities_2_3` named set, this named set remains available for the length of the current MDX session. The following example is a valid query that would return City 2 and City 3 members, and that could be run anytime after you create the `SetCities_2_3` named set and before the session closes.

```
select SetCities_2_3 on 0 from [Store]
```

MDX Calculated Members - Building Calculated Members

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

In Multidimensional Expressions (MDX), a calculated member is a member that is resolved by calculating an MDX expression to return a value. This innocuous definition covers an incredible amount of ground. The ability to construct and use calculated members in an MDX query provides a great deal of manipulation capability for multidimensional data.

You can create calculated members at any point within a hierarchy. You can also create calculated members that depend not only on existing members in a cube, but also on other calculated members defined in the same MDX expression.

You can define a calculated member to have one of the following contexts:

- **Query-scoped** To create a calculated member that is defined as part of an MDX query, and therefore whose scope is limited to the query, you use the WITH keyword. You can then use the calculated member within an MDX SELECT statement. Using this approach, the calculated member created by using the WITH keyword can be changed without disturbing the SELECT statement.

For more information about how to use the WITH keyword to create calculated members, see [Creating Query-Scoped Calculated Members \(MDX\)](#).

- **Session-scoped** To create a calculated member whose scope is wider than the context of the query, that is, whose scope is the lifetime of the MDX session, you use the CREATE MEMBER statement. A calculated member defined by using the CREATE MEMBER statement is available to all MDX queries in that session. The CREATE MEMBER statement makes sense, for example, in a client application that consistently reuses the same set in a variety of queries.

For more information about how to use the CREATE MEMBER statement to create calculated members in a session, see [Creating Session-Scope Calculated Members \(MDX\)](#).

MDX Calculated Members - Query-Scoped Calculated Members

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

If a calculated member is only required for a single Multidimensional Expressions (MDX) query, you can define that calculated member by using the WITH keyword. A calculated member that is created by using the WITH keyword no longer exists after the query has finished running.

As discussed in this topic, the syntax of the WITH keyword is quite flexible, even allowing a calculated member to be based on another calculated member.

Note

For more information about calculated members, see [Building Calculated Members in MDX \(MDX\)](#).

WITH Keyword Syntax

Use the following syntax to add the WITH keyword to an MDX SELECT statement:

```
[ WITH <SELECT WITH clause> [ , <SELECT WITH clause> ... ] ] SELECT [ * | (
<SELECT query axis clause> [ , <SELECT query axis clause> ... ] ) ]FROM
<SELECT subcube clause> [ <SELECT slicer axis clause> ][ <SELECT cell
property list clause> ]
<SELECT WITH clause> ::=
( [ CALCULATED ] MEMBER <CREATE MEMBER body clause>) | <CREATE MEMBER
body clause> ::= Member_Identifier AS 'MDX_Expression'
[ <CREATE MEMBER property clause> [ , <CREATE MEMBER property clause> ...
] ]
<CREATE MEMBER property clause> ::=
( MemberProperty_Identifier = Scalar_Expression )
```

In the syntax for the WITH keyword, the `Member_Identifier` value is the fully qualified name of the calculated member. This fully qualified name includes the dimension or level to which the calculated member is associated. The `MDX_Expression` value returns

the value of the calculated member after the expression value has been evaluated. The values of intrinsic cell properties for a calculated member can be optionally specified by supplying the name of the cell property in the `MemberProperty_Identifier` value and the value of the cell property in the `Scalar_Expression` value.

WITH Keyword Examples

The following MDX query defines a calculated member, `[Measures].[Special Discount]`, calculating a special discount based on the original discount amount.

```
WITH
  MEMBER [Measures].[Special Discount] AS
    [Measures].[Discount Amount] * 1.5
SELECT
  [Measures].[Special Discount] ON COLUMNS,
  NON EMPTY [Product].[Product].MEMBERS ON Rows
FROM [Adventure Works]
WHERE [Product].[Category].[Bikes]
```

You can also create calculated members at any point within a hierarchy. For example, the following MDX query defines the `[BigSeller]` calculated member for a hypothetical Sales cube. This calculated member determines whether a specified store has at least 100.00 in unit sales for beer and wine. However, the query creates the `[BigSeller]` calculated member not as a child member of the `[Product]` dimension, but instead as a child member of the `[Beer and Wine]` member.

```
WITH
  MEMBER [Product].[Beer and Wine].[BigSeller] AS
    IIf([Product].[Beer and Wine] > 100, "Yes", "No")
SELECT
  {[Product].[BigSeller]} ON COLUMNS,
  Store.[Store Name].Members ON ROWS
FROM Sales
```

Calculated members do not have to depend only on existing members in a cube. Calculated member can also be based on other calculated members defined in the same MDX expression. For example, the following MDX query uses the value created in the first calculated member, `[Measures].[Special Discount]`, to generate the value of the second calculated member, `[Measures].[Special Discounted Amount]`.

```
WITH
    MEMBER [Measures].[Special Discount] AS
        [Measures].[Discount Percentage] * 1.5,
        FORMAT_STRING = 'Percent'

    MEMBER [Measures].[Special Discounted Amount] AS
        [Measures].[Reseller Average Unit Price] * [Measures].[Special Discount],
        FORMAT_STRING = 'Currency'

SELECT
    {[Measures].[Special Discount], [Measures].[Special Discounted Amount]}
on COLUMNS,
    NON EMPTY [Product].[Product].MEMBERS ON Rows
FROM [Adventure Works]
WHERE [Product].[Category].[Bikes]
```

MDX Calculated Members - Session-Scope Calculated Members

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

To create a calculated member that is available throughout a Multidimensional Expressions (MDX) session, you use the [CREATE MEMBER](#) statement. A calculated member that is created by using the CREATE MEMBER statement will not be removed until after the MDX session closes.

As discussed in this topic, the syntax of the CREATE MEMBER statement is straightforward and easy to use.

Note

For more information about calculated members, see [Building Calculated Members in MDX \(MDX\)](#).

CREATE MEMBER Syntax

Use the following syntax to add the CREATE MEMBER statement to the MDX statement:

```
CREATE [SESSION] MEMBER [<cube-name>.]<fully-qualified-member-name> AS  
<expression> [,<property-definition-list>]  
<cube name> ::= CURRENTCUBE | <Cube Name>  
<property-definition-list> ::= <property-definition>  
| <property-definition>, <property-definition-list>  
<property-definition> ::= <property-identifier> = <property-value>  
<property-identifier> ::= VISIBLE | SOLVEORDER | SOLVE_ORDER | FORMAT_STRING  
| NON_EMPTY_BEHAVIOR <ole db member properties>
```

In the syntax for the CREATE MEMBER statement, the `fully-qualified-member-name` value is the fully qualified name of the calculated member. The fully qualified name includes the dimension or level to which the calculated member is associated. The `expression` value returns the value of the calculated member after the `expression` value has been evaluated.,

CREATE MEMBER Example

The following example uses the CREATE MEMBER statement to create the `LastFourStores` calculated member. This calculated member returns the sum of units sold for the last four stores, and will be available throughout the whole session of the cube.

```
Create Session Member [Store].[Measures].LastFourStores as  
sum(([Stores].[ByLocation].Lag(3) :  
[Stores].[ByLocation].NextMember), [Measures].[Units Sold])
```

MDX Cell Calculations - Build Cell Calculations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Multidimensional Expressions (MDX) provides you with a number of tools for generating calculated values, such as calculated members, custom rollups, and custom members. However, using these features to affect a specific set of cells, or a single cell for that matter, would be difficult.

To generate calculated values specifically for cells, you need to use the calculated cells feature in MDX. Calculated cells let you define a specific slice of cells, called a *calculation subcube*, and apply a formula to each and every cell within the calculation subcube, subject to an optional condition that can be applied to each cell.

Calculated cells also offer complex functionality, such as goal-seeking formulas, as used in KPIs, or speculative analysis formulas. This level of functionality comes from the pass order feature in Microsoft SQL Server SQL Server Analysis Services that allows recursive passes to be made with calculated cells, with calculation formulas applied at specific passes in the pass order. For more information on pass order, see [Understanding Pass Order and Solve Order \(MDX\)](#).

In terms of creation scope, calculated cells are similar to both named sets and calculated members in that calculated cells can be temporarily created for the lifetime of either a session or a single query, or made globally available as part of a cube:

- **Query-scoped** To create a calculated cell that is defined as part of an MDX query, and therefore whose scope is limited to the query, you use the **WITH** keyword. You can then use the calculated cell within an MDX SELECT statement. Using this approach, the calculated cell created by using the **WITH** keyword can be changed without disturbing the SELECT statement.

For more information about how to use the **WITH** keyword to create calculated members, see [Creating Query-Scoped Cell Calculations \(MDX\)](#).

- **Session-scoped** To create a calculated member whose scope is wider than the context of the query, that is, whose scope is the lifetime of the MDX session, you use either the CREATE CELL CALCULATION or ALTER CUBE statement.

For more information about how to use either the CREATE CELL CALCULATION or ALTER CUBE statement to create calculated cells in a session, see [Creating Session-Spaced Calculated Cells](#)

MDX Cell Calculations - Query-Scoped Cell Calculations

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

You use the **WITH** keyword in Multidimensional Expressions (MDX) to describe calculated cells within the context of a query. The **WITH** keyword has the following syntax:

```
WITH CELL CALCULATION Cube_Name.CellCalc_Identifier  String_Expression
```

The `CellCalc_Identifier` value is the name of the calculated cells. The `String_Expression` value contains a list of orthogonal, single-dimensional MDX set expressions. Each of these set expressions must resolve to one of the categories listed in the following table.

 Expand table

Category	Description
Empty set	An MDX set expression that resolves into an empty set. In this case, the scope of the calculated cell is the whole cube.
Single member set	An MDX set expression that resolves into a single member.
Set of level members	An MDX set expression that resolves into the members of a single level. An example of such a set expression is the <code>Level_Expression.Members</code> MDX function. To include calculated members, use the <code>Level_Expression.AllMembers</code> MDX function. For more information, see AllMembers (MDX) .
Set of descendants	An MDX set expression that resolves into the descendants of a specified member. An example of such a set expression is the <code>Descendants(Member_Expression, Level_Expression, Desc_Flag)</code> MDX function. For more information, see Descendants (MDX) .

If the `String_Expression` argument does not describe a dimension, MDX assumes that all members are included for the purposes of constructing the calculation subcube.

Therefore, if the `String_Expression` argument is NULL, the calculated cells definition applies to the whole cube.

The `MDX_Expression` argument contains an MDX expression that evaluates to a cell value for all the cells defined in the `String_Expression` argument.

Additional Considerations

MDX processes the calculation condition, specified by the **CONDITION** property, only once. This single processing provides increased performance for the evaluation of multiple calculated cells definitions, especially with overlapping calculated cells across cube passes.

When this single processing occurs depends on the creation scope of the calculated cells definition:

- If created at global scope, as part of a cube, MDX process the calculation condition when the cube is processed. If cells are modified in the cube in any way, and the cells are included in the calculation subcube of a calculated cells definition, the calculation condition may not be accurate until the cube is reprocessed. Cell modification can occur from writebacks, for example. The calculation condition is reprocessed when the cube is reprocessed.
- If created at session scope, MDX process the calculation condition when the statement is issued during the session. As with calculated cells definitions created globally, if the cells are modified, the calculation condition may not be accurate for the calculated cells definition.
- If created at query scope, MDX processes the calculation condition when the query runs. The cell modification issue applies here, also, although data latency issues are minimal because of the low processing time of MDX query execution.

On the other hand, MDX processes the calculation formula whenever an MDX query is issued against the cube involving cells included in the calculated cells definition. This processing occurs regardless of the creation scope.

MDX Cell Calculations - Session-Scoped Calculated Cells

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Important

This syntax has been deprecated. You should use MDX assignments should instead. For more information on assignments, see [The Basic MDX Script \(MDX\)](#).

To create calculated cells that are available to all queries in the same session, you can use either the [CREATE CELL CALCULATION](#) statement or the [ALTER CUBE](#) statement. Both statements have the same result.

CREATE CELL CALCULATION Syntax

Important

This syntax has been deprecated. You should use MDX assignments should instead. For more information on assignments, see [The Basic MDX Script \(MDX\)](#).

Use the following syntax to use the CREATE CELL CALCULATION statement to define a session-scoped calculated cell:

```
CREATE CELL CALCULATION Cube_Expression.<CREATE CELL CALCULATION body clause>

<CREATE CELL CALCULATION body clause> ::=CellCalc_Identifier FOR
String_Expression AS 'MDX_Expression'
[ <CREATE CELL CALCULATION property clause> [ , <CREATE CELL CALCULATION property clause> ... ] ]

<CREATE CELL CALCULATION property clause> ::=
( CONDITION = 'Logical_Expression' ) |
( DISABLED = { TRUE | FALSE } ) |
( DESCRIPTION =String_Expression ) |
( CALCULATION_PASS_NUMBER = Integer_Expression ) |
( CALCULATION_PASS_DEPTH = Integer_Expression ) |
```

```
( SOLVE_ORDER = Integer_Expression ) |
( FORMAT_STRING = String_Expression ) |
( CellProperty_Identifier = Scalar_Expression )
```

ALTER CUBE Syntax

Important

This syntax has been deprecated. You should use MDX assignments instead.

For more information on assignments, see [The Basic MDX Script \(MDX\)](#).

Use the following syntax to use the ALTER CUBE statement to define a session-scoped calculated cell:

```
ALTER CUBE Cube_Identifier CREATE CELL CALCULATION
FOR String_Expression AS 'MDX_Expression'
    [ <CREATE CELL CALCULATION property clause> [ , <CREATE CELL CALCULATION
property clause> ... ] ]

<CREATE CELL CALCULATION property clause> ::=
    ( CONDITION = 'Logical_Expression' ) |
    ( DISABLED = { TRUE | FALSE } ) |
    ( DESCRIPTION =String_Expression ) |
    ( CALCULATION_PASS_NUMBER = Integer_Expression ) |
    ( CALCULATION_PASS_DEPTH = Integer_Expression ) |
    ( SOLVE_ORDER = Integer_Expression ) |
    ( FORMAT_STRING = String_Expression ) |
    ( CellProperty_Identifier = Scalar_Expression )
```

The `String_Expression` value contains a list of orthogonal, single-dimensional MDX set expressions, each of which must resolve to one of the categories of sets that are listed in the following table.

 Expand table

Category	Description
Empty set	An MDX set expression that resolves into an empty set. In this case, the scope of the calculated cell is the whole cube.
Single member set	An MDX set expression that resolves into a single member.

Category	Description
Set of level members	<p>An MDX set expression that resolves into the members of a single level. An example of this is the <code>Level_Expression.Members</code> MDX function. To include calculated members, use the <code>Level_Expression.AllMembers</code> MDX function.</p> <p>For more information, see AllMembers (MDX).</p>
Set of descendants	<p>An MDX set expression that resolves into the descendants of a specified member. An example of this is the <code>Descendants(Member_Expression, Level_Expression, Desc_Flag)</code> MDX function.</p> <p>For more information, see Descendants (MDX).</p>

MDX Building Measures

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

In Multidimensional Expressions (MDX), a measure is a named DAX expression that is resolved by calculating the expression to return a value in a Tabular Model. This innocuous definition covers an incredible amount of ground. The ability to construct and use measures in an MDX query provides a great deal of manipulation capability for tabular data.

Warning

Measures can only be defined in tabular models; if your database is set in multidimensional mode, creating a measure will generate an error

To create a measure that is defined as part of an MDX query, and therefore whose scope is limited to the query, you use the WITH keyword. You can then use the measure within an MDX SELECT statement. Using this approach, the calculated member created by using the WITH keyword can be changed without disturbing the SELECT statement. However, in MDX you reference the measure in a different way than when in DAX expressions; to reference the measure you name it as a member of the [Measures] dimension, see the following MDX example:

```
with measure 'Sales Territory'[Total Sales Amount] = SUM('Internet Sales'[Sales Amount]) + SUM('Reseller Sales'[Sales Amount])
select measures.[Total Sales Amount] on columns
    ,NON EMPTY [Date].[Calendar Year].children on rows
from [Model]
```

It will return the following data when executed:

 Expand table

Year	Total Sales Amount
2001	11331808.96

Year	Total Sales Amount
2002	30674773.18
2003	41993729.72
2004	25808962.34

MDX Member Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Member properties cover the basic information about each member in each tuple. This basic information includes the member name, parent level, the number of children, and so on. Member properties are available for all members at a given level. In terms of organization, member properties are treated as dimensionally organized data, stored on a single dimension.

Note

In MicrosoftSQL Server, member properties are known as attribute relationships. For more information, see [Attribute Relationships](#).

Member properties are either *intrinsic* or *custom*:

Intrinsic member properties

All members support intrinsic member properties, such as the formatted value of a member, while dimensions and levels supply additional intrinsic dimension and level member properties, such as the ID of a member.

For more information, see [Intrinsic Member Properties \(MDX\)](#).

User-defined member properties

Members often have additional properties associated with them. For example, the Products level may offer the SKU, SRP, Weight, and Volume properties for each product. These properties are not members, but contain additional information about members at the Products level.

For more information, see [User-Defined Member Properties \(MDX\)](#).

Both intrinsic and user-defined member properties can be retrieved through the use of the **PROPERTIES** keyword or the [Properties](#) function.

Using the PROPERTIES Keyword

The **PROPERTIES** keyword specifies the member properties that are to be used for a given axis dimension. The **PROPERTIES** keyword is buried within the `<axis>`

`<axis_specification>` clause of the MDX **SELECT** statement:

```
SELECT [<axis_specification>
        [, <axis_specification>...]]
  FROM [<cube_specification>]
 [WHERE [<slicer_specification>]]
```

The `<axis_specification>` clause includes an optional `<dim_props>` clause, as shown in the following syntax:

```
<axis_specification> ::= <set> [<dim_props>] ON <axis_name>
```

ⓘ Note

For more information about the `<set>` and `<axis_name>` values, see [Specifying the Contents of a Query Axis \(MDX\)](#).

The `<dim_props>` clause lets you query dimension, level, and member properties using the **PROPERTIES** keyword. The following syntax shows the formatting of the `<dim_props>` clause:

```
<dim_props> ::= [DIMENSION] PROPERTIES <property> [,<property>...]
```

The breakdown of the `<property>` syntax varies depending on the property that you are querying:

- Context sensitive intrinsic member properties must be preceded with the name of the dimension or level. However, non-context sensitive intrinsic member properties cannot be qualified by the dimension or level name. For more information about how to use the **PROPERTIES** keyword with intrinsic member properties, see [Intrinsic Member Properties \(MDX\)](#).
- User-defined member properties should be preceded by the name of the level in which they reside. For more information about how to use the **PROPERTIES** keyword with user-defined member properties, see [User-Defined Member Properties \(MDX\)](#).

MDX Member Properties - Intrinsic Member Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

SQL Server Analysis Services exposes intrinsic properties on dimension members that you can include in a query to return additional data or metadata for use in a custom application, or to assist in model investigation or construction. If you are using the SQL Server client tools, you can view intrinsic properties in SQL Server Management Studio (SSMS).

Intrinsic properties include **ID**, **KEY**, **KEYx**, and **NAME**, which are properties exposed by every member, at any level. You can also return positional information, such as **LEVEL_NUMBER** or **PARENT_UNIQUE_NAME**, among others.

Depending on how you construct the query, and on the client application you are using to execute queries, member properties may or may not be visible in the result set. If you are using SQL Server Management Studio to test or run queries, you can double-click a member in the result set to open the Member Properties dialog box, showing the values for each intrinsic member property.

For an introduction to using and viewing dimension member properties, see [Viewing SSAS Member Properties within an MDX Query Window in SSMS](#).

Note

As a provider that is compliant with the OLAP section of the OLE DB specification dated March 1999 (2.6), Microsoft SQL Server SQL Server Analysis Services supports the intrinsic member properties listed in this topic.

Providers other than SQL ServerSQL Server Analysis Services may support additional intrinsic member properties. For more information about the intrinsic member properties supported by other providers, refer to the documentation that comes with those providers.

Types of Member Properties

The intrinsic member properties supported by SQL Server SQL Server Analysis Services are of two types:

Context sensitive member properties

These member properties must be used in the context of a specific hierarchy or level, and supply values for each member of the specified dimension or level.

Notice how the following example includes the path for the **KEY** property: `MEMBER [Measures].[Parent Member Key] AS [Product].[Product Categories].CurrentMember.Parent.PROPERTIES("KEY")`.

Non-context sensitive member properties

These member properties cannot be used in the context of a specific dimension or level, and return values for all members on an axis.

Context-insensitive properties standalone and do not include path information. Notice how there is no dimension or level specified for **PARENT_UNIQUE_NAME** in the following example: `DIMENSION PROPERTIES PARENT_UNIQUE_NAME ON COLUMNS`

Regardless of whether the intrinsic member property is context sensitive or not, the following usage rules apply:

- You can specify only those intrinsic member properties that relate to dimension members that are projected on the axis.
- You can mix requests for context sensitive member properties in the same query with non-context sensitive intrinsic member properties.
- You use the **PROPERTIES** keyword to query for the properties.

The following sections describe both the various context sensitive and non-context sensitive intrinsic member properties available in SQL Server SQL Server Analysis Services, and how to use the **PROPERTIES** keyword with each type of property.

Context Sensitive Member Properties

All dimension members and level members support a list of intrinsic member properties that are context sensitive. The following table lists these context-sensitive properties.

[] Expand table

Property	Description
ID	The internally maintained ID for the member.

Property	Description
Key	The value of the member key in the original data type. MEMBER_KEY is for backward-compatibility. MEMBER_KEY has the same value as KEY0 for non-composite keys, and MEMBER_KEY property is null for composite keys.
KEYx	<p>The key for the member, where x is the zero-based ordinal of the key. KEY0 is available for composite and non-composite keys, but primarily used for composite keys.</p> <p>For composite keys, KEY0, KEY1, KEY2, and so on, collectively form the composite key. You can use each one independently in a query to return that portion of the composite key. For example, specifying KEY0 returns the first part of the composite key, specifying KEY1 returns the next part of the composite key, and so on.</p> <p>If the key is non-composite, then KEY0 is equivalent to Key.</p> <p>Note that KEYx can be used in context as well as without context. For this reason, it appears in both lists.</p> <p>For an example of how to use this member property, see A Simple MDX Tidbit: Key0, Key1, Key2 ↴.</p>
Name	The name of the member.

PROPERTIES Syntax for Context Sensitive Properties

You use these member properties in the context of a specific dimension or level, and supply values for each member of the specified dimension or level.

For dimension member properties, you precede the name of the property with the name of the dimension to which the property applies. The following example shows the appropriate syntax:

```
DIMENSION PROPERTIES Dimension.Property_name
```

For a level member property, you can precede the name of the property with just the level name or, for additional specification, both the dimension and level name. The following example shows the appropriate syntax:

```
DIMENSION PROPERTIES [Dimension.]Level.Property_name
```

To illustrate, you would like to return all the names of each referenced member in the [Sales] dimension. To return these names, you would use the following statement in a Multidimensional Expressions (MDX) query:

Non-Context Sensitive Member Properties

All members support a list of intrinsic member properties that are the same regardless of context. These properties provide additional information that can be used by applications to enhance the user's experience.

The following table lists the non-context sensitive intrinsic properties supported by SQL Server SQL Server Analysis Services.

 **Note**

Columns in the **MEMBERS** schema rowset support the intrinsic member properties listed in the following table. For more information about the **MEMBERS** schema rowset, see [MDSHEMA_MEMBERS](#) rowset.

 [Expand table](#)

Property	Description
CATALOG_NAME	The name of the cube to which this member belongs.
CHILDREN_CARDINALITY	The number of children that the member has. This can be an estimate, so you should not rely on this to be the exact count. Providers should return the best estimate possible.
CUSTOM_ROLLUP	The custom member expression.
CUSTOM_ROLLUP_PROPERTIES	The custom member properties.
DESCRIPTION	A human-readable description of the member.
DIMENSION_UNIQUE_NAME	The unique name of the dimension to which this member belongs. For providers that generate unique names by qualification, each component of this name is delimited.
HIERARCHY_UNIQUE_NAME	The unique name of the hierarchy. If the member belongs to more than one hierarchy, there is one row for each hierarchy to which the member belongs. For providers that generate unique names by qualification, each component of this name is delimited.
IS_DATAMEMBER	A Boolean that indicates whether the member is a data member.

Property	Description
IS_PLACEHOLDERMEMBER	A Boolean that indicates whether the member is a placeholder.
KEYx	<p>The key for the member, where x is the zero-based ordinal of the key. KEY0 is available for composite and non-composite keys.</p> <p>If the key is non-composite, then KEY0 is equivalent to Key.</p> <p>For composite keys, KEY0, KEY1, KEY2, and so on, collectively form the composite key. You can reference each one independently in a query to return that portion of the composite key. For example, specifying KEY0 returns the first part of the composite key, specifying KEY1 returns the next part of the composite key, and so on.</p> <p>Note that KEYx can be used in context as well as without context. For this reason, it appears in both lists.</p> <p>For an example of how to use this member property, see A Simple MDX Tidbit: Key0, Key1, Key2 ↴.</p>
LCID x	<p>The translation of the member caption in the locale ID hexadecimal value, where x is the locale ID decimal value (for example, LCID1009 as English-Canada). This is only available if the translation has the caption column bound to the data source.</p>
LEVEL_NUMBER	<p>The distance of the member from the root of the hierarchy. The root level is zero.</p>
LEVEL_UNIQUE_NAME	<p>The unique name of the level to which the member belongs. For providers that generate unique names by qualification, each component of this name is delimited.</p>
MEMBER_CAPTION	<p>A label or caption associated with the member. The caption is primarily for display purposes. If a caption does not exist, the query returns MEMBER_NAME.</p>
MEMBER_KEY	<p>The value of the member key in the original data type. MEMBER_KEY is for backward-compatibility. MEMBER_KEY has the same value as KEY0 for non-composite keys, and MEMBER_KEY property is null for composite keys.</p>
MEMBER_NAME	<p>The name of the member.</p>
MEMBER_TYPE	<p>The type of the member. This property can have one of the following values:</p> <p style="text-align: center;">MDMEMBER_TYPE_REGULAR</p>

Property	Description
	MDMEMBER_TYPE_ALL MDMEMBER_TYPE_FORMULA MDMEMBER_TYPE_MEASURE MDMEMBER_TYPE_UNKNOWN
	<p>Note: MDMEMBER_TYPE_FORMULA takes precedence over MDMEMBER_TYPE_MEASURE. Therefore, if there is a formula (calculated) member on the Measures dimension, the MEMBER_TYPE property for the calculated member is MDMEMBER_TYPE_FORMULA.</p>
MEMBER_UNIQUE_NAME	The unique name of the member. For providers that generate unique names by qualification, each component of this name is delimited.
MEMBER_VALUE	The value of the member in the original type.
PARENT_COUNT	The number of parents that this member has.
PARENT_LEVEL	The distance of the member's parent from the root level of the hierarchy. The root level is zero.
PARENT_UNIQUE_NAME	The unique name of the member's parent. NULL is returned for any members at the root level. For providers that generate unique names by qualification, each component of this name is delimited.
SKIPPED_LEVELS	The number of skipped levels for the member.
UNARY_OPERATOR	The unary operator for the member.
UNIQUE_NAME	The fully-qualified name of the member, in this format: [dimension].[level].[key6.]

PROPERTIES Syntax for Non-Context Sensitive Properties

Use the following syntax to specify an intrinsic, non-context sensitive member property using the **PROPERTIES** keyword:

DIMENSION PROPERTIES Property

Notice that this syntax does not allow the property to be qualified by a dimension or level. The property cannot be qualified because an intrinsic member property that is not context sensitive applies to all members of an axis.

For example, an MDX statement that specifies the **DESCRIPTION** intrinsic member property would have the following syntax:

```
DIMENSION PROPERTIES DESCRIPTION
```

This statement returns the description of each member in the axis dimension. If you tried to qualify the property with a dimension or level, as in *Dimension .DESCRIPTION* or *Level .DESCRIPTION*, the statement would not validate.

Example

The following examples show MDX queries that return intrinsic properties.

Example 1: Use context-sensitive intrinsic properties in query

The following example returns parent ID, key, and name for each product category. Notice how the properties are exposed as measures. This lets you view the properties in a cellset when you run the query, rather than the Member Properties dialog in SSMS. You might run a query like this to retrieve member metadata from a cube that is already deployed.

```
WITH
MEMBER [Measures].[Parent Member ID] AS
    [Product].[Product Categories].CurrentMember.Parent.PROPERTIES("ID")
MEMBER [Measures].[Parent Member Key] AS
    [Product].[Product Categories].CurrentMember.Parent.PROPERTIES("KEY")
MEMBER [Measures].[Parent Member Name] AS
    [Product].[Product Categories].CurrentMember.Parent.PROPERTIES("Name")
SELECT
    {[Measures].[Parent Member ID], [Measures].[Parent Member Key], [Measures].[Parent Member Name]} on COLUMNS,
    [Product].[Product Categories].AllMembers on ROWS
FROM [Adventure Works]
```

Example 2: Non-context-sensitive intrinsic properties

The following example is the full list of non-context-sensitive intrinsic properties. After running the query in SSMS, click individual members to view properties in the Member Properties dialog box.

```

SELECT [Measures].[Sales Amount Quota] on COLUMNS,
[Employee].[Employees].members
DIMENSION PROPERTIES
    CATALOG_NAME ,
    CHILDREN_CARDINALITY ,
    CUSTOM_ROLLUP ,
    CUSTOM_ROLLUP_PROPERTIES ,
    DESCRIPTION ,
    DIMENSION_UNIQUE_NAME ,
    HIERARCHY_UNIQUE_NAME ,
    IS_DATAMEMBER ,
    IS_PLACEHOLDERMEMBER ,
    KEY0 ,
    LCID ,
    LEVEL_NUMBER ,
    LEVEL_UNIQUE_NAME ,
    MEMBER_CAPTION ,
    MEMBER_KEY ,
    MEMBER_NAME ,
    MEMBER_TYPE ,
    MEMBER_UNIQUE_NAME ,
    MEMBER_VALUE ,
    PARENT_COUNT ,
    PARENT_LEVEL ,
    PARENT_UNIQUE_NAME ,
    SKIPPED_LEVELS ,
    UNARY_OPERATOR ,
    UNIQUE_NAME
ON ROWS
FROM [Adventure Works]
WHERE [Employee].[Employee Department].[Department].&[Sales]

```

Example 3: Return member properties as data in a result set

The following example returns the translated caption for the product category member in the Product dimension in the Adventure Works cube for specified locales.

```

WITH
MEMBER Measures.CategoryCaption AS
Product.Category.CurrentMember.MEMBER_CAPTION
MEMBER Measures.SpanishCategoryCaption AS
Product.Category.CurrentMember.Properties("LCID3082")
MEMBER Measures.FrenchCategoryCaption AS
Product.Category.CurrentMember.Properties("LCID1036")
SELECT
{ Measures.CategoryCaption, Measures.SpanishCategoryCaption,
Measures.FrenchCategoryCaption } ON 0
,[Product].[Category].MEMBERS ON 1

```

FROM [Adventure Works]

MDX Member Properties - User-Defined Member Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

User-defined member properties can be added to a specific named level in a dimension as attribute relationships. User-defined member properties cannot be added to the (All) level of a hierarchy, or to the hierarchy itself.

Creating User-Defined Member Properties

User-defined member properties can be added to server-based dimensions or cubes either through the user interface or programmatically:

- To add user-defined member properties through the user interface, you use Dimension Designer in SQL Server Data Tools. For more information, see [Define Attribute Relationships](#).
- To add user-defined member properties programmatically, your application can use either Analysis Manager Objects (AMO) or a combination of XML for Analysis (XMLA) and Analysis Services Scripting Language (ASSL). For more information, see [Attribute Relationships](#).

Retrieving User-Defined Member Properties

You can retrieve user-defined member properties using either the **PROPERTIES** keyword or the [Properties](#) function.

Using the PROPERTIES Keyword to Retrieve User-Defined Member Properties

The syntax that retrieves user-defined member properties is similar to that used to retrieve intrinsic level member properties, as shown in the following syntax:

```
DIMENSION PROPERTIES [Dimension.]Level.<Custom_Member_Property>
```

The **PROPERTIES** keyword appears after the set expression of the axis specification. For example, the following MDX query the **PROPERTIES** keyword retrieves the [List Price](#)

and `Dealer Price` user-defined member properties and appears after the set expression that identifies the products sold in January:

```
SELECT
    CROSSJOIN([Ship Date].[Calendar].[Calendar Year].Members,
              [Measures].[Sales Amount]) ON COLUMNS,
    NON EMPTY Product.Product.MEMBERS
    DIMENSION PROPERTIES
        Product.Product.[List Price],
        Product.Product.[Dealer Price] ON ROWS
FROM [Adventure Works]
WHERE ([Date].[Month of Year].[January])
```

Using the Properties Function to Retrieve User-Defined Member Properties

Alternatively, you can access custom member properties with the **Properties** function. For example, the following MDX query uses the **WITH** keyword to create a calculated member consisting of the `List Price` member property:

```
WITH
    MEMBER [Measures].[Product List Price] AS
        [Product].[Product].CurrentMember.Properties("List Price")
SELECT
    [Measures].[Product List Price] on COLUMNS,
    [Product].[Product].MEMBERS ON Rows
FROM [Adventure Works]
```

For more information about building calculated members, see [Building Calculated Members in MDX \(MDX\)](#).

MDX Cell Properties - Using Cell Properties

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Cell properties in Multidimensional Expressions (MDX) contain information about the content and format of cells in a multidimensional data source, such as a cube.

MDX supports the CELL PROPERTIES keyword in an MDX SELECT statement to retrieve intrinsic cell properties. Intrinsic cell properties are most commonly used to assist in the visual presentation of cell data.

CELL PROPERTIES Keyword Syntax

Use the following syntax for the **CELL PROPERTIES** keyword of the MDX **SELECT** statement:

```
SELECT [<axis_specification>
        [, <axis_specification>...]]
    FROM [<cube_specification>]
[WHERE [<slicer_specification>]]
[<cell_props>]
```

The following syntax shows the format of the `<cell_props>` value and how this value uses the **CELL PROPERTIES** keyword along with one or more intrinsic cell properties:

```
<cell_props> ::= CELL PROPERTIES <property> [, <property>...]
```

Supported Intrinsic Cell Properties

The following table lists the supported intrinsic cell properties that are used in the `<property>` value.

 Expand table

Property	Description
ACTION_TYPE	<p>A bitmask that indicates which types of actions exist on the cell. This property can have one of the following values:</p> <ul style="list-style-type: none"> <li data-bbox="473 294 760 328">MDACTION_TYPE_URL <li data-bbox="473 384 791 418">MDACTION_TYPE_HTML <li data-bbox="473 474 871 508">MDACTION_TYPE_STATEMENT <li data-bbox="473 564 823 597">MDACTION_TYPE_DATASET <li data-bbox="473 654 823 687">MDACTION_TYPE_ROWSET <li data-bbox="473 744 923 777">MDACTION_TYPE_COMMANDLINE <li data-bbox="473 834 887 867">MDACTION_TYPE_PROPRIETARY <li data-bbox="473 923 812 957">MDACTION_TYPE_REPORT <li data-bbox="473 1013 919 1047">MDACTION_TYPE_DRILLTHROUGH <p>Note: Drillthrough actions are not included for queries containing a set in the where clause.</p>
BACK_COLOR	<p>The background color for displaying the VALUE or FORMATTED_VALUE property. For more information, see FORE_COLOR and BACK_COLOR Contents (MDX).</p>
CELL_ORDINAL	<p>The ordinal number of the cell in the dataset.</p>
FONT_FLAGS	<p>The bitmask detailing effects on the font. The value is the result of a bitwise OR operation of one or more of the following constants:</p> <ul style="list-style-type: none"> <li data-bbox="473 1620 680 1654">MDFF_BOLD = 1 <li data-bbox="473 1710 696 1744">MDFF_ITALIC = 2 <li data-bbox="473 1800 764 1834">MDFF_UNDERLINE = 4 <li data-bbox="473 1890 760 1924">MDFF_STRIKEOUT = 8 <p>For example, the value 5 represents the combination of bold (MDFF_BOLD) and underline (MDFF_UNDERLINE) font effects.</p>

Property	Description
FONT_NAME	The font to be used to display the VALUE or FORMATTED_VALUE property.
FONT_SIZE	Font size to be used to display the VALUE or FORMATTED_VALUE property.
FORE_COLOR	The foreground color for displaying the VALUE or FORMATTED_VALUE property. For more information, see FORE_COLOR and BACK_COLOR Contents (MDX) .
FORMAT	Same as FORMAT_STRING .
FORMAT_STRING	The format string used to create the FORMATTED_VALUE property value. For more information, see FORMAT_STRING Contents (MDX) .
FORMATTED_VALUE	The character string that represents a formatted display of the VALUE property.
LANGUAGE	The locale where the FORMAT_STRING will be applied. LANGUAGE is usually used for currency conversion.
UPDATEABLE	A value that indicates whether the cell can be updated. This property can have one of the following values:
	MD_MASK_ENABLED (0x00000000) The cell can be updated.
	MD_MASK_NOT_ENABLED (0x10000000) The cell cannot be updated.
	CELL_UPDATE_ENABLED (0x00000001) Cell can be updated in the cellset.
	CELL_UPDATE_ENABLED_WITH_UPDATE (0x00000002) The cell can be updated with an update statement. The update may fail if a leaf cell is updated that is not write-enabled.
	CELL_UPDATE_NOT_ENABLED_FORMULA (0x10000001) The cell cannot be updated because the cell has a calculated member among its coordinates; the cell was retrieved with a set in the where clause. A cell can be updated even though a formula affects, or a calculated cell is on, the value of a cell (is somewhere along the aggregation path). In this scenario, the final value of the cell may not be the updated value, because the calculation will affect the result
	CELL_UPDATE_NOT_ENABLED_NONSUM_MEASURE (0x10000002) The cell cannot be updated because non-sum measures (count, min, max, distinct count, semi-additive) can not be updated.
	CELL_UPDATE_NOT_ENABLED_NACELL_VIRTUALCUBE (0x10000003) The cell cannot be updated because the cell does not exist as it is at the intersection of a measure and a dimension member unrelated to the measure's measure group.

Property	Description
	CELL_UPDATE_NOT_ENABLED_SECURE (0x10000005) The cell cannot be updated because the cell is secured.
	CELL_UPDATE_NOT_ENABLED_CALCLEVEL (0x10000006) Reserved for future use.
	CELL_UPDATE_NOT_ENABLED_CANNOTUPDATE (0x10000007) The cell cannot be updated because of internal reasons.
	CELL_UPDATE_NOT_ENABLED_INVALIDDIMENSIONTYPE (0x10000009) The cell cannot be updated because update is not supported in mining model, indirect, or data mining dimensions.
VALUE	The unformatted value of the cell.

Only the **CELL_ORDINAL**, **FORMATTED_VALUE**, and **VALUE** cell properties are required. All cell properties, intrinsic or provider-specific, are defined in the **PROPERTIES** schema rowset, including their data types and provider support.

By default, if the **CELL PROPERTIES** keyword is not used, the cell properties returned are **VALUE**, **FORMATTED_VALUE**, and **CELL_ORDINAL** (in that order). If the **CELL PROPERTIES** keyword is used, only those cell properties explicitly stated with the keyword are returned.

The following example demonstrates the use of the **CELL PROPERTIES** keyword in an MDX query:

```

SELECT
  {[Measures].[Reseller Gross Profit]} ON COLUMNS,
  {[Reseller].[Reseller Type].[Reseller Name].Members} ON ROWS
FROM [Adventure Works]
CELL PROPERTIES VALUE, FORMATTED_VALUE, FORMAT_STRING, FORE_COLOR,
BACK_COLOR

```

Cell properties are not returned for MDX queries that return flattened rowsets; in this case, each cell is represented as if only the **FORMATTED_VALUE** cell property were returned.

Setting Cell Properties

Cell properties can be set in Microsoft SQL Server SQL Server Analysis Services in various places. For example, the Format String property can be set for regular measures on the

Cube Structure tab of the Cube Editor in SQL Server Data Tools; the same property can be set for calculated measures defined on the cube on the Calculations tab of the Cube Editor; calculated measures defined in the WITH clause of a query have their format string defined there too. The following query demonstrates how cell properties can be set on a calculated measure::

```
WITH MEMBER MEASURES.CELLPROPERTYDEMO AS [Measures].[Internet Sales Amount]
, FORE_COLOR=RGB(0,0,255)
, BACK_COLOR=IIF([Measures].[Internet Sales Amount]>7000000, RGB(255,0,0),
RGB(0,255,0))
, FONT_SIZE=10
, FORMAT_STRING='#,#.000'
SELECT MEASURES.CELLPROPERTYDEMO ON 0,
[Date].[Calendar Year].[Calendar Year].MEMBERS ON 1
FROM [Adventure Works]
CELL PROPERTIES VALUE, FORMATTED_VALUE, FORE_COLOR, BACK_COLOR, FONT_SIZE
```

MDX Cell Properties - FORMAT_STRING Contents

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

The **FORMAT_STRING** cell property formats the **VALUE** cell property, creating the value for the **FORMATTED_VALUE** cell property. The **FORMAT_STRING** cell property handles both string and numeric raw values, applying a format expression against the value to return a formatted value for the **FORMATTED_VALUE** cell property. The following tables detail the syntax and formatting characters used to handle string and numeric values.

String Values

A format expression for strings can have one section or two sections separated by a semicolon (;).

 Expand table

Usage	Result
One section	The format applies to all string values.
Two sections	The first section applies to string data, whereas the second section applies to null values and zero-length strings ("").

The characters described in the following table can appear in the format string for character strings.

 Expand table

Character	Description
@	Represents a character placeholder that displays a character or a space. If the string has a character in the position where the at sign (@) appears in the format string, the formatted string displays the character. Otherwise, the formatted string displays a space in that position. Placeholders are filled from right to left unless there is an exclamation point (!) in the format string.
&	Represents a character placeholder that displays a character or nothing. If the string has a character in the position where the ampersand (&) appears, the formatted

Character	Description
	string displays the character. Otherwise, the formatted string displays nothing. Placeholders are filled from right to left unless there is an exclamation point (!) in the format string.
<	Forces lowercase. The formatted string displays all characters in lowercase format.
>	Forces uppercase. The formatted string displays all characters in uppercase format.
!	Forces left-to-right fill of placeholders. (The default is to fill placeholders from right to left.)

Numeric Values

A user-defined format expression for numbers can have anywhere from one to four sections separated by semicolons. If the format argument contains one of the named numeric formats, only one section is allowed.

[Expand table](#)

Usage	Result
One section	The format expression applies to all values.
Two sections	The first section applies to positive values and zeros, the second to negative values.
Three sections	The first section applies to positive values, the second to negative values, and the third to zeros.
Four sections	The first section applies to positive values, the second to negative values, the third to zeros, and the fourth to null values.

The following example has two sections. The first section defines the format for positive values and zeros, and the second section defines the format for negative values.

```
"$#,##0;($#,##0)"
```

If you include semicolons with nothing between them, the missing section prints using the format of the positive value. For example, the following format displays positive and negative values using the format in the first section and displays "Zero" if the value is zero:

```
"$#,##0; ;\Z\ e\r\o"
```

The following table identifies the characters that can appear in the format string for numeric formats.

[Expand table](#)

Character	Description
None	Displays the number without any formatting.
0	<p>Represents a digit placeholder that displays a digit or a zero (0).</p> <p>If the number has a digit in the position where the zero appears in the format string, the formatted value displays the digit. Otherwise, the formatted value displays a zero in that position.</p> <p>If the number has fewer digits than there are zeros (on either side of the decimal) in the format string, the formatted value displays leading or trailing zeros.</p> <p>If the number has more digits to the right of the decimal separator than there are zeros to the right of the decimal separator in the format expression, the formatted value rounds the number to as many decimal places as there are zeros.</p> <p>If the number has more digits to the left of the decimal separator than there are zeros to the left of the decimal separator in the format expression, the formatted value displays the additional digits without modification.</p>
#	<p>Represents a digit placeholder that displays a digit or nothing.</p> <p>If the expression has a digit in the position where the number sign (#) appears in the format string, the formatted value displays the digit. Otherwise, the formatted value displays nothing in that position.</p> <p>The number sign (#) placeholder works like the zero (0) digit placeholder except that leading and trailing zeros are not displayed if the number has the same or fewer digits than there are # characters on either side of the decimal separator in the format expression.</p>
.	<p>Represents a decimal placeholder that determines how many digits are displayed to the left and right of the decimal separator.</p> <p>If the format expression contains only number sign (#) characters to the left of the period (.), numbers smaller than 1 start with a decimal separator. To display a leading zero displayed with fractional numbers, use zero (0) as the first digit placeholder to the left of the decimal separator.</p>
The actual character used as a decimal placeholder in the formatted output depends	

Character	Description
	<p>on the number format recognized by the computer system.</p> <p>Note: In some locales, a comma is used as the decimal separator.</p>
%	<p>Represents a percentage placeholder. The expression is multiplied by 100. The percent character (%) is inserted in the position where the percentage appears in the format string.</p>
,	<p>Represents a thousand separator that separates thousands from hundreds within a number that has four or more places to the left of the decimal separator.</p> <p>Standard use of the thousand separator is specified if the format contains a thousand separator enclosed in digit placeholders (0 or #).</p>
	<p>Two adjacent thousand separators, or a thousand separator immediately to the left of the decimal separator (whether or not a decimal is specified), means "scale the number by dividing the number by 1000, rounding as required." For example, you can use the format string "##0,," to represent 100 million as 100. Numbers smaller than 1 million are displayed as 0. Two adjacent thousand separators in any position other than immediately to the left of the decimal separator are treated as specifying the use of a thousand separator.</p>
	<p>The actual character used as the thousand separator in the formatted output depends on the number format recognized by the computer system.</p> <p>Note: In some locales, a period is used as the thousand separator.</p>
:	<p>Represents a time separator that separates hours, minutes, and seconds when time values are formatted.</p> <p>Note: In some locales, other characters may be used as the time separator.</p> <p>The actual character used as the time separator in formatted output is determined by the system settings on the computer.</p>
/	<p>Represents a date separator that separates the day, month, and year when date values are formatted.</p> <p>The actual character used as the date separator in formatted output is determined by the system settings on the computer.</p> <p>Note: In some locales, other characters may be used as the date separator.</p>
E- E+ e- e+	<p>Represents scientific format.</p> <p>If the format expression contains at least one digit placeholder (0 or #) to the right of E-, E+, e-, or e+, the formatted value displays in scientific format and E or e is inserted between the number and the number's exponent. The number of digit placeholders to the right determines the number of digits in the exponent. Use E- or</p>

Character	Description
e-	to include a minus sign next to negative exponents. Use E+ or e+ to include a minus sign next to negative exponents and a plus sign next to positive exponents.
- + \$ ()	Displays a literal character. To display a character other than one of those listed, put a backslash (\) before the character or enclose the character in double quotation marks (" ").
\	Displays the next character in the format string. To display a character that has special meaning as a literal character, put a backslash (\) before the character. The backslash itself is not displayed. Using a backslash is the same as enclosing the next character in double quotation marks. To display a backslash, use two backslashes (\\). Examples of characters that cannot be displayed as literal characters include the following characters: The date-formatting and time-formatting characters-a, c, d, h, m, n, p, q, s, t, w, y, /, and : The numeric-formatting characters-#, 0, %, E, e, comma, and period The string-formatting characters-@, &, <, >, and !
"ABC"	Displays the string inside the double quotation marks (" "). To include a string in format from within code, use Chr(34) to enclose the text. (The character code for a double quotation mark is 34.)

Named Numeric Formats

The following table identifies the predefined numeric format names:

[+] Expand table

Format name	Description
General	Displays the number with no thousand separator.
Number	
Currency	Displays the number with a thousand separator, if appropriate. Displays two digits to the right of the decimal separator. Output is based on system locale settings.
Fixed	Displays at least one digit to the left and two digits to the right of the decimal

Format name	Description
	separator.
Standard	Displays the number with thousand separator, at least one digit to the left and two digits to the right of the decimal separator.
Percent	Displays the number multiplied by 100 with a percent sign (%) appended to the right. Always displays two digits to the right of the decimal separator.
Scientific	Uses standard scientific notation.
Yes/No	Displays No if the number is 0; otherwise, displays Yes.
True/False	Displays False if the number is 0; otherwise, displays True.
On/Off	Displays Off if the number is 0; otherwise, displays On.

Date Values

The following table identifies characters that can appear in the format string for date/time formats.

[\[+\] Expand table](#)

Character	Description
:	<p>Represents a time separator that separates hours, minutes, and seconds when time values are formatted.</p> <p>The actual character used as the time separator in formatted output is determined by the system settings of the computer.</p> <p>Note: In some locales, other characters may be used as the time separator.</p>
/	<p>Represents a date separator that separates the day, month, and year when date values are formatted.</p> <p>The actual character used as the date separator in formatted output is determined by the system settings of the computer.</p> <p>Note: In some locales, other characters may be used to represent the date separator.</p>
C	<p>Displays the date as dddddd and displays the time as ttttt, in that order.</p> <p>Displays only date information if there is no fractional part to the date serial number.</p> <p>Displays only time information if there is no integer portion.</p>

Character	Description
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat).
ddd d	Displays the day as a full name (Sunday-Saturday).
dd d	Displays the date as a complete date (including day, month, and year), formatted according to your system's short date format setting. For Microsoft Windows, the default short date format is m/d/yy .
dd d dd	Displays a date serial number as a complete date (including day, month, and year), formatted according to the long date setting recognized by the computer system. For Windows, the default long date format is mmmm dd, yyyy .
w	Displays the day of the week as a number (1 for Sunday through 7 for Saturday).
ww	Displays the week of the year as a number (1-54).
m	Displays the month as a number without a leading zero (1-12). If m immediately follows h or hh , the minute instead of the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If m immediately follows h or hh , the minute instead of the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec).
mmmm	Displays the month as a full month name (January-December).
q	Displays the quarter of the year as a number (1-4).
y	Displays the day of the year as a number (1-366).
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (100-9999).
h	Displays the hour as a number without leading zeros (0-23).
hh	Displays the hour as a number with leading zeros (00-23).
n	Displays the minute as a number without leading zeros (0-59).
nn	Displays the minute as a number with leading zeros (00-59).
s	Displays the second as a number without leading zeros (0-59).

Character	Description
ss	Displays the second as a number with leading zeros (00-59).
t t t t	Displays a time as a complete time (including hour, minute, and second), formatted using the time separator defined by the time format recognized by the computer system. A leading zero is displayed if the leading zero option is selected, and the time is earlier than 10:00 in either the A.M. or the P.M. cycle. For example, 09:59, For Windows, the default time format is h:mm:ss .
AM/PM	Displays an uppercase AM with any hour from midnight until noon; displays an uppercase PM with any hour from noon until midnight. Note: Uses the 12-hour clock.
am/pm	Displays a lowercase am with any hour from midnight until noon; displays a lowercase pm with any hour from noon until midnight. Note: Uses the 12-hour clock.
A/P	Displays an uppercase A with any hour from midnight until noon; displays an uppercase P with any hour from noon until midnight. Note: Uses the 12-hour clock.
a/p	Displays a lowercase a with any hour from midnight until noon; displays a lowercase p with any hour from noon until midnight. Note: Uses the 12-hour clock.
AMPM	Displays the AM string literal as defined by the computer system with any hour from midnight until noon; displays the PM string literal as defined by the computer system with any hour from noon until midnight. AMPM can be either uppercase or lowercase, but the case of the string displayed matches the string as defined by the system settings of the computer. For Windows, the default format is AM/PM . Note: Uses the 12-hour clock.

Named Date Formats

The following table identifies the predefined date and time format names:

Format	Description
Name	
General Date	Displays a date and/or time. For real numbers, displays a date and time, for example, 4/3/93 05:34 PM. If there is no fractional part, displays only a date, for example, 4/3/93. If there is no integer part, displays a time only, for example, 05:34 PM. The format of the date display is determined by your system settings.
Long Date	Displays a date according to your system's long date format.
Medium Date	Displays a date using the medium date format appropriate for the language version of the host application.
Short Date	Displays a date using your system's short date format.
Long Time	Displays a time using your system's long time format; includes hours, minutes, and seconds.
Medium Time	Displays a time in the 12-hour format using hours and minutes and the AM/PM designator.
Short Time	Displays a time using the 24-hour format, for example, 17:45.

MDX Cell Properties - FORE_COLOR and BACK_COLOR Contents

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

The **FORE_COLOR** and **BACK_COLOR** cell properties store color information for the text and the background of a cell, respectively, in the Microsoft Windows operating system red-green-blue (RGB) format.

The valid range for an ordinary RGB color is zero (0) to 16,777,215 (&H00FFFFFF). The high byte of a number in this range always equals 0; the lower 3 bytes, from least to most significant byte, determine the amount of red, green, and blue, respectively. The red, green, and blue components are each represented by a number between 0 and 255 (&HFF).

MDX Cell Properties - FORMATTED_VALUE Property

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

The FORMATTED_VALUE property is built on the interactions of the VALUE, FORMAT_STRING and LANGUAGE properties of the cell. This topic explains how these properties interact to build the FORMATTED_VALUE property.

VALUE, FORMAT_STRING, LANGUAGE properties

The following table explains what these properties are, to help prepare us to use them in combination.

VALUE

The unformatted value of the cell.

FORMAT_STRING

The formatting template to be applied to the value of the cell to generate FORMATTED_VALUE property

LANGUAGE

The locale specification to be applied alongside FORMAT_STRING to generate a localized version of FORMATTED_VALUE

FORMATTED_VALUE constructed

The FORMATTED_VALUE property is constructed by using the value from the VALUE property and applying the format template specified in the FORMAT_STRING property to that value. In addition, whenever the formatting value is a **named formatting literal** the LANGUAGE property specification modifies the output of FORMAT_STRING to follow the language usage for the named formatting. Named formatting literals are all defined in a way that can be localized. For example, "General Date" is a specification that can be localized, as opposed to the following template "YYYY-MM-DD hh:nn:ss", which states that the date is to be presented as defined by the template regardless of the language specification.

If there is a conflict between the FORMAT_STRING template and the LANGUAGE specification, the FORMAT_STRING template overrides the LANGUAGE specification. For example, if FORMAT_STRING="\$ #0" and LANGUAGE=1034 (Spain), and VALUE=123.456 then FORMATTED_VALUE="\$ 123" instead of FORMATTED_VALUE="€ 123", the expected format is in Euros, because the value of the format template overrides the language specified.

Examples

The following examples show the output obtained when LANGUAGE is used in conjunction with FORMAT_STRING.

The first example explains formatting numerical values; the second example explains formatting date and time values.

For each example the Multidimensional Expressions (MDX) code is given.

with

```
member measures.A as 5040, FORMAT_STRING="Currency"

member measures.B as measures.A, LANGUAGE=1034

member measures.C as measures.A, LANGUAGE=1034 , FORMAT_STRING="#,##0.00"

member measures.D as measures.A, FORMAT_STRING="Scientific"

member measures.E as measures.A, LANGUAGE=1034 , FORMAT_STRING="Scientific"

member measures.F as 0.5040, FORMAT_STRING="Percent"

member measures.G as measures.F, LANGUAGE=1034

member measures.H as 0, LANGUAGE=1034 , FORMAT_STRING="Yes/No"

member measures.I as 59, LANGUAGE=1034 , FORMAT_STRING="Yes/No"

member measures.J as 0, LANGUAGE=1034 , FORMAT_STRING="ON/OFF"

member measures.K as -312, LANGUAGE=1034 , FORMAT_STRING="ON/OFF"

Select {measures.A, measures.B, measures.C, measures.D, measures.E, measures.F,
measures.G, measures.H, measures.I, measures.J, measures.K} on 0

from [Adventure Works]
```

```
cell properties VALUE, FORMAT_STRING, LANGUAGE, FORMATTED_VALUE
```

The results, transposed, when the above MDX query was run using SQL Server Management Studio over a server and client with locale 1033 are as follows:

[+] Expand table

Member	FORMATTED_VALUE	Explanation
A	\$5,040.00	FORMAT_STRING is set to <code>Currency</code> and LANGUAGE is <code>1033</code> , inherited from system locale value
B	€5.040,00	FORMAT_STRING is set to <code>Currency</code> (inherited from A) and LANGUAGE is explicitly set to <code>1034</code> (Spain) hence the Euro sign, the different decimal separator and the different thousand separator.
C	\$5.040,00	FORMAT_STRING is set to <code>\$#,##0.00</code> an override to Currency, from A, and LANGUAGE is explicitly set to <code>1034</code> (Spain). Because the FORMAT_STRING property explicitly set the currency symbol to \$, the FORMATTED_VALUE is presented with the \$ sign. However, because <code>.</code> (dot) and <code>,</code> (comma) are placeholders for decimal separator and thousand separator respectively, the language specification affects them generating an output that is localized for decimal and thousand separators.
D	5.04E+03	FORMAT_STRING is set to <code>Scientific</code> and LANGUAGE is set to <code>1033</code> , inherited from system locale value, hence <code>.</code> (dot) is the decimal separator.
E	5,04E+03	FORMAT_STRING is set to <code>Scientific</code> and LANGUAGE is set explicitly to <code>1034</code> , hence <code>,</code> (comma) is the decimal separator.
F	50.40%	FORMAT_STRING is set to <code>Percent</code> and LANGUAGE is set to <code>1033</code> , inherited from system locale value, hence <code>.</code> (dot) is the decimal separator. Note that VALUE was changed from 5040 to 0.5040
G	50,40%	FORMAT_STRING is set to <code>Percent</code> , inherited from F, and LANGUAGE is set explicitly to <code>1034</code> hence <code>,</code> (comma) is the decimal separator. Note that VALUE was inherited from F value.
H	No	FORMAT_STRING is set to <code>YES/NO</code> , VALUE is set to 0 and LANGUAGE is set explicitly to <code>1034</code> ; because there is no

Member	FORMATTED_VALUE	Explanation
		difference between English NO and Spanish NO the user sees no difference in the FORMATTED_VALUE.
I	SI	FORMAT_STRING is set to YES/NO, VALUE is set to 59 and LANGUAGE is set explicitly to 1034; as defined for YES/NO formatting, any value different from zero (0) is a YES and because language is set to Spanish then the FORMATTED_VALUE is SI.
J	Desactivado	FORMAT_STRING is set to ON/OFF, VALUE is set to 0 and LANGUAGE is set explicitly to 1034; as defined for ON/OFF formatting, any value equal to zero (0) is an OFF and because language is set to Spanish then the FORMATTED_VALUE is Desactivado.
K	Activado	FORMAT_STRING is set to ON/OFF, VALUE is set to -312 and LANGUAGE is set explicitly to 1034; as defined for ON/OFF formatting, any value different from zero (0) is an ON and because language is set to Spanish then the FORMATTED_VALUE is Activado.

with

```

member measures.A as 'CDate("1959-03-12 06:30")'

MDX Data Manipulation - Manipulating Data

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Multidimensional Expressions (MDX) can be used to manipulate the data in a variety of ways. The following topics cover some of the more advanced concepts of data manipulation in the MDX language

In This Section

 Expand table

Topic	Description
Using DRILLTHROUGH to Retrieve Source Data (MDX)	Discusses the use of the MDX DRILLTHROUGH statement to retrieve the rowsets of source data applicable to a cell in a multidimensional data source
Working with the RollupChildren Function (MDX)	Discusses the impact of the MDX RollupChildren function on the analysis of multidimensional data.
Understanding Pass Order and Solve Order (MDX)	Details the concepts of solve order, and how this feature affects MDX expressions, statements, and scripts.

MDX Data Manipulation - Retrieve Source Data Using DRILLTHROUGH

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Multidimensional Expressions (MDX) uses the [DRILLTHROUGH](#) statement to retrieve a rowset from the source data for a cube cell.

In order to run a **DRILLTHROUGH** statement on a cube, a drillthrough action must be defined for that cube. To define a drillthrough action, in SQL Server Data Tools, in Cube Designer, on the **Actions** pane, on the toolbar, click **New Drillthrough Action**. In the new drillthrough action, specify the action name, target, condition, and the columns that are returned by a **DRILLTHROUGH** statement.

DRILLTHROUGH Statement Syntax

The **DRILLTHROUGH** statement uses the following syntax:

```
<drillthrough> ::= DRILLTHROUGH [<Max_Rows>] [<First_Rowset>] <MDX select>
[<Return_Columns>]
  < Max_Rows > ::= MAXROWS <positive number>
  <First_Rowset> ::= FIRSTROWSET <positive number>
  <Return_Columns> ::= RETURN <member or attribute> [, <member or
attribute>]
```

The **SELECT** clause identifies the cube cell that contains the source data to be retrieved. This **SELECT** clause is the same to an ordinary MDX **SELECT** statement, except that in the **SELECT** clause only one member can be specified on each axis. If more than one member is specified on an axis, an error occurs.

The **<Max_Rows>** syntax specifies the maximum number of the rows in each returned rowset. If the OLE DB provider that is used to connect to the data source does not support **DBPROP_MAXROWS**, the **<Max_Rows>** setting is ignored.

The **<First_Rowset>** syntax identifies the partition whose rowset is returned first.

The **<Return_Columns>** syntax identifies the underlying database columns to be returned.

DRILLTHROUGH Statement Example

The following example demonstrates the use of the DRILLTHROUGH statement. In this example, the DRILLTHROUGH statement queries the leaves of the Store, Product, and Time dimensions along the Stores dimension (the slicer axis), and then returns the department measure group, department ID, and employee's first name.

```
DRILLTHROUGH  
Select {Leaves(Store), Leaves(Product), Leaves(Time),*} on 0  
From Stores  
RETURN [Department MeasureGroup].[Department Id], [Employee].[First Name]
```

MDX Data Manipulation - RollupChildren Function

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

The Multidimensional Expressions (MDX) [RollupChildren](#) function rolls up the children of a member, applying a different unary operator to each child, and returns the value of this rollup as a number. The unary operator can be supplied by a member property associated with the child member, or the operator can be a string expression provided directly to the function.

RollupChildren Function Examples

The use of the **RollupChildren** function in Multidimensional Expressions (MDX) statements is simple to explain, but the effect of this function on MDX queries can be wide-ranging.

The effect of the **RollupChildren** function occurs in MDX queries designed to perform selective analysis on existing cube data. For example, the following table contains a list of child members for the Net Sales parent member, with their unary operators (represented by the **UNARY_OPERATOR** member property) shown in parentheses.

 Expand table

Parent member	Child member
Net Sales	Domestic Sales (+)
	Domestic Returns (-)
	Foreign Sales (+)
	Foreign Returns (-)

The Net Sales parent member currently provides a total of net sales minus the gross domestic and foreign sales values, with the domestic and foreign returns subtracted as part of the rollup.

However, you want to provide a quick and easy forecast of domestic and foreign gross sales plus 10%, ignoring the domestic and foreign returns. To calculate this value, you

can use the `RollupChildren` function in one of two ways: with a custom member property or with the `IIf` function.

Using a Custom Member Property

If the rollup calculation is to be a frequently performed operation, one method is to create a member property that stores the operator that will be used for each child for a specific function. The following table displays valid unary operators and describes the expected result.

[\[+\] Expand table](#)

Operator	Result
+	total = total + current child
-	total = total - current child
*	total = total * current child
/	total = total / current child
~	Child is not used in the rollup. The child's value is ignored.

For example, a member property called `SALES_OPERATOR` could be created, and the following unary operators would be assigned to that member property, as shown in the following table.

[\[+\] Expand table](#)

Parent member	Child member
Net Sales	Domestic Sales (+)
	Domestic Returns (~)
	Foreign Sales (+)
	Foreign Returns (~)

With this new member property, the following MDX statement would perform the gross sales estimate operation quickly and efficiently (ignoring Foreign and Domestic returns):

```
RollupChildren([Net Sales], [Net  
Sales].CurrentMember.Properties("SALES_OPERATOR")) * 1.1
```

When the function is called, the value of each child is applied to a total using the operator stored in the member property. The members for domestic and foreign returns are ignored, and the rollup total returned by the **RollupChildren** function is multiplied by 1.1.

Using the **IIf** Function

If the example operation is not commonplace or if the operation applies only to one MDX query, the **IIf** function can be used with the **RollupChildren** function to provide the same result. The following MDX query provides the same result as the earlier MDX example, but does so without resorting to the use of a custom member property:

```
RollupChildren([Net Sales], IIf([Net  
Sales].CurrentMember.Properties("UNARY_OPERATOR") = "-", "~", [Net  
Sales].CurrentMember.Properties("UNARY_OPERATOR))) * 1.1
```

The MDX statement examines the unary operator of the child member. If the unary operator is used for subtraction (as in the case with the domestic and foreign returns members), the **IIf** function substitutes the tilde (~) unary operator. Otherwise, the **IIf** function uses the unary operator of the child member. Finally, the returned rollup total is then multiplied by 1.1 to provide the domestic and foreign gross sales forecast value.

MDX Data Manipulation - Understanding Pass Order and Solve Order

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

When a cube is calculated as the result of an MDX script, it can go through many stages of computation depending on the use of various calculation-related features. Each of these stages is referred to as a calculation pass.

A calculation pass can be referred to by an ordinal position, called the calculation pass number. The count of calculation passes that are required to fully compute all the cells of a cube is referred to as the calculation pass depth of the cube.

Fact table and writeback data only impact pass 0. Scripts populate data after pass 0; each assignment and calculate statement in a script creates a new pass. Outside the MDX script, references to absolute pass 0 refer to the last pass created by the script for the cube.

Calculated members are created at all passes, but the expression is applied at the current pass. Prior passes contain the calculated measure, but with a null value.

Solve Order

Solve order determines the priority of calculation in the event of competing expressions. Within a single pass, solve order determines two things:

- The order in which Microsoft SQL Server SQL Server Analysis Services evaluates dimensions, members, calculated members, custom rollups, and calculated cells.
- The order in which SQL Server Analysis Services calculates custom members, calculated members, custom rollup, and calculated cells.

The member with the highest solve order takes precedence.

Note

The exception to this precedence is the Aggregate function. Calculated members with the Aggregate function have a lower solve order than any intersecting calculated measure.

Solve Order Values and Precedence

Solve order values can range from -8181 to 65535. In this range, some solve order values correspond to specific kinds of calculations, as shown in the following table.

[Expand table](#)

Calculation	Solve Order
Custom member formulas	-5119
Unary operators	-5119
Visual totals calculation	-4096
All other calculations (if not otherwise specified)	0

It is highly recommended that you use only positive integers when setting solve order values. If you assign values that are lower than the solve order values shown in the previous table, the calculation pass can become unpredictable. For example, the calculation for a calculated member receives a solve order value that is lower than the default custom rollup formula value of -5119. Such a low solve order value causes the calculated members to be calculated before the custom rollup formulas, and can produce incorrect results.

Creating and Changing Solve Order

In Cube Designer, on the **Calculations Pane**, you can change the solve order for calculated members and calculated cells by changing the order of the calculations.

In MDX, you can use the **SOLVE_ORDER** keyword to create or change calculated members and calculated cells.

Solve Order Examples

To illustrate the potential complexities of solve order, the following series of MDX queries starts with two queries that each individually have no solve order issues. These two queries are then combined into a query that requires solve order.

Query 1-Differences in Income and Expenses

For the first MDX query, calculate the difference in sales and costs for each year by constructing a simple MDX query similar to the following example:

```
WITH
MEMBER
[Date].[Calendar].[Year Difference] AS ([Date].[Calendar].[Calendar Year].&
[2008] - [Date].[Calendar].[Calendar Year].&[2007] )
SELECT
{[Measures].[Internet Sales Amount], [Measures].[Internet Total Product
Cost] }
ON COLUMNS ,
{ [Date].[Calendar].[Calendar Year].&[2007], [Date].[Calendar].[Calendar
Year].&[2008], [Date].[Year Difference] }
ON ROWS
FROM [Adventure Works]
```

In this query, there is only one calculated member, `Year Difference`. Because there is only one calculated member, solve order is not an issue, as long as the cube does not use any calculated members.

This MDX query produces a result set similar to the following table.

[Expand table](#)

	Internet Sales Amount	Internet Total Product Cost
CY 2007	\$9,791,060.30	\$5,718,327.17
CY 2008	\$9,770,899.74	\$5,721,205.24
Year Difference	(\$20,160.56)	\$2,878.06

Query 2-Percentage of Income after Expenses

For the second query, calculate the percentage of income after expenses for each year using the following MDX query:

```
WITH
MEMBER
[Measures].[Profit Margin] AS
([Measures].[Internet Sales Amount] - [Measures].[Internet Total Product
```

```

Cost] ) / [Measures].[Internet Sales Amount] ,
FORMAT_STRING="Percent"
SELECT
{[Measures].[Internet Sales Amount], [Measures].[Internet Total Product
Cost], [Measures].[Profit Margin] }
ON COLUMNS ,
{ [Date].[Calendar].[Calendar Year].&[2007], [Date].[Calendar].[Calendar
Year].&[2008] }
ON ROWS
FROM [Adventure Works]

```

This MDX query, like the previous one, has only a single calculated member, **Profit Margin**, and therefore does not have any solve order complications.

This MDX query produces a slightly different result set, similar to the following table.

 Expand table

	Internet Sales Amount	Internet Total Product Cost	Profit Margin
CY 2007	\$9,791,060.30	\$5,718,327.17	41.60%
CY 2008	\$9,770,899.74	\$5,721,205.24	41.45%

The difference in result sets between the first query and the second query comes from the difference in placement of the calculated member. In the first query, the calculated member is part of the ROWS axis, not the COLUMNS axis shown in the second query. This difference in placement becomes important in the next query, which combines the two calculated members in a single MDX query.

Query 3-Combined Year Difference and Net Income Calculations

In this final query combining both of the previous examples into a single MDX query, solve order becomes important because of the calculations on both columns and rows. To make sure that the calculations occur in the correct sequence, define the sequence in which the calculations occur by using the **SOLVE_ORDER** keyword.

The **SOLVE_ORDER** keyword specifies the solve order of calculated members in an MDX query or a **CREATE MEMBER** command. The integer values used with the **SOLVE_ORDER** keyword are relative, do not need to start at zero, and do not need to be consecutive. The value simply tells MDX to calculate a member based on values derived from calculating members with a higher value. If a calculated member is defined without the **SOLVE_ORDER** keyword, the default value of that calculated member is zero.

For example, if you combine the calculations used in the first two example queries, the two calculated members, `Year Difference` and `Profit Margin`, intersect at a single cell in the result dataset of the MDX query example. The only way to determine how SQL Server Analysis Services will evaluate this cell is by the solve order. The formulas that are used to construct this cell will produce different results depending upon the solve order of the two calculated members.

First, try combining the calculations used in the first two queries in the following MDX query:

```
WITH
MEMBER
[Date].[Calendar].[Year Difference] AS ([Date].[Calendar].[Calendar Year].&
[2008] - [Date].[Calendar].[Calendar Year].&[2007] ) ,
SOLVE_ORDER = 1
MEMBER
[Measures].[Profit Margin] AS
( [Measures].[Internet Sales Amount] - [Measures].[Internet Total Product
Cost] ) / [Measures].[Internet Sales Amount] ,
FORMAT_STRING="Percent" ,
SOLVE_ORDER = 2
SELECT
{[Measures].[Internet Sales Amount], [Measures].[Internet Total Product
Cost], [Measures].[Profit Margin] }
ON COLUMNS ,
{ [Date].[Calendar].[Calendar Year].&[2007], [Date].[Calendar].[Calendar
Year].&[2008], [Date].[Year Difference] }
ON ROWS
FROM [Adventure Works]
```

In this combined MDX query example, `Profit Margin` has the highest solve order, so it takes precedence when the two expressions interact. SQL Server Analysis Services evaluates the cell in question by using the `Profit Margin` formula. The results of this nested calculation, as shown in the following table.

[Expand table](#)

	Internet Sales Amount	Internet Total Product Cost	Profit Margin
CY 2007	\$9,791,060.30	\$5,718,327.17	41.60%
CY 2008	\$9,770,899.74	\$5,721,205.24	41.45%
Year Difference	(\$20,160.56)	\$2,878.06	114.28%

The result in the shared cell is based on the formula for **Profit Margin**. That is, SQL Server Analysis Services calculates the result in the shared cell with the **Year Difference** data, producing the following formula (the result is rounded for clarity):

```
((9,770,899.74 - 9,791,060.30) - (5,721,205.24 - 5,718,327.17)) /  
(9,770,899.74 - 9,791,060.30) = 1.14275744
```

or

```
(23,038.63) / (20,160.56) = 114.28%
```

This is clearly incorrect. However, SQL Server Analysis Services calculates the result in the shared cell differently if you switch the solve orders for the calculated members in the MDX query. The following combined MDX query reverses the solve order for the calculated members:

```
WITH  
MEMBER  
[Date].[Calendar].[Year Difference] AS ([Date].[Calendar].[Calendar Year].&  
[2008] - [Date].[Calendar].[Calendar Year].&[2007] ) ,  
SOLVE_ORDER = 2  
MEMBER  
[Measures].[Profit Margin] AS  
( [Measures].[Internet Sales Amount] - [Measures].[Internet Total Product  
Cost] ) / [Measures].[Internet Sales Amount] ,  
FORMAT_STRING="Percent" ,  
SOLVE_ORDER = 1  
SELECT  
{[Measures].[Internet Sales Amount], [Measures].[Internet Total Product  
Cost], [Measures].[Profit Margin] }  
ON COLUMNS ,  
{ [Date].[Calendar].[Calendar Year].&[2007], [Date].[Calendar].[Calendar  
Year].&[2008], [Date].[Year Difference] }  
ON ROWS  
FROM [Adventure Works]
```

As the order of the calculated members has been switched, SQL Server Analysis Services uses the **Year Difference** formula to evaluate the cell, as shown in the following table.

 Expand table

	Internet Sales Amount	Internet Total Product Cost	Profit Margin
CY 2007	\$9,791,060.30	\$5,718,327.17	41.60%
CY 2008	\$9,770,899.74	\$5,721,205.24	41.45%
Year Difference	(\$20,160.56)	\$2,878.06	(0.15%)

Because this query uses the `Year Difference` formula with the `Profit Margin` data, the formula for the shared cell resembles the following calculation:

$$((\$9,770,899.74 - 5,721,205.24) / \$9,770,899.74) - ((9,791,060.30 - 5,718,327.17) / 9,791,060.30) = -0.15$$

Or

$$0.4145 - 0.4160 = -0.15$$

Additional Considerations

Solve order can be a very complex issue to deal with, especially in cubes with a high number of dimensions involving calculated member, custom rollup formulas, or calculated cells. When SQL Server Analysis Services evaluates an MDX query, SQL Server Analysis Services takes into account the solve order values for everything involved within a given pass, including the dimensions of the cube specified in the MDX query.

MDX Data Modification - Modifying Data

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Besides using Multidimensional Expressions (MDX) to retrieve and handle data from dimensions and cubes, you can use MDX to update or *writeback* dimension and cube data. These updates can be temporary, as with speculative, or "what if", analysis, or permanent, as when changes must occur based upon data analysis.

Updates to data can occur at the dimension or cube level:

Dimension writebacks

You use the [ALTER CUBE Statement \(MDX\)](#) statement to change a write-enabled dimension's data and the [REFRESH CUBE Statement \(MDX\)](#) to reflect the deletion, creation, and updating of attribute values. You can also use the ALTER CUBE statement to perform complex operations, such as deleting a whole sub-tree in a hierarchy and promoting the children of a deleted member.

Cube writebacks

You use the [UPDATE CUBE](#) statement to make updates to a write-enabled cube. The UPDATE CUBE statement lets you update a tuple with a specific value. You use the [REFRESH CUBE Statement \(MDX\)](#) to refresh data in a client session with updated data from the server.

For more information, see [Using Cube Writebacks \(MDX\)](#).

MDX Data Modification - Using Cube Writebacks

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

You update a cube by using the [UPDATE CUBE](#) statement. This statement lets you update a tuple with a specific value. To effectively use the UPDATE CUBE statement to update a cube, you have to understand the syntax for the statement, the error conditions that can occur, and the affect that updates can have on a cube.

UPDATE CUBE Statement Syntax

The following syntax describes the UPDATE CUBE statement:

```
UPDATE [CUBE] <Cube_Name> SET <tuple>.VALUE = <value> [,<tuple>.VALUE =  
<value>...]  
[ USE_EQUAL_ALLOCATION | USE_EQUAL_INCREMENT |  
USE_WEIGHTED_ALLOCATION [BY <weight value_expression>] |  
USE_WEIGHTED_INCREMENT [BY <weight value_expression>] ]
```

If a full set of coordinates is not specified for the tuple, the unspecified coordinates will use the default member of the hierarchy. The tuple identified must reference a cell that is aggregated with the [Sum](#) function, and must not use a calculated member as one of the cell's coordinates.

You can think of the UPDATE CUBE statement as a subroutine that generates a series of individual writeback operations to atomic cells. All these individual writeback operations then roll up into the specified sum.

Note

When updated cells do not overlap, the [Update Isolation Level](#) connection string property can be used to enhance performance for UPDATE CUBE. For more information, see [ConnectionString](#).

Example

You can test UPDATE CUBE using the Sales Targets measure group in the Adventure Works cube. This measure group consists of measures aggregated by SUM, which is a requirement for UPDATE CUBE.

1. Enable writeback for the Sales Targets measure group in the Adventure Works database. In Management Studio, right-click a measure group, point to **Write Back Options**, choose **Enable Writeback**.

You should see a new writeback table in the Writeback folder. The table name is WriteTable_Fact Sales Quota.

2. Open an MDX query window. Run the following select statement to view the original value:

```
SELECT [Measures].[Sales Amount Quota] on 0 ,  
[Employee].[Employee Department].[Title].&[Sales  
Representative].children on 1  
FROM [Adventure Works]
```

You should see sales amount quotas for each representative.

3. Run the update cube statement to write back a new value. In this example, we are setting the sales amount quota to 0. Because the new value is 0, do not specify an allocation method.

```
UPDATE CUBE [Adventure Works]  
SET ([Measures].[Sales Amount Quota], [Employee].[Employee Department].  
[Department].&[Sales]) = 0
```

4. Re-run the SELECT statement. You should now see zero for the quotas.

The writeback value is constrained to the current session. To persist the value across users and sessions, process the writeback table. In Management Studio, right-click WriteTable_Fact Sales Quota and choose **Process**.

To specify an allocation method, the new value must be greater than zero. In this example, the new value for Sales Amount Quota is two million and the allocation

method distributes the amount across all sales representatives.

```
UPDATE CUBE [Adventure Works]
SET ([Measures].[Sales Amount Quota], [Employee].[Employee Department].[Department].&[Sales]) = 2000000
USE_EQUAL_ALLOCATION
```

Error Conditions

The following table describes both what can cause writebacks to fail and the result of those errors.

[\[+\] Expand table](#)

Error Condition	Result
Update includes members from the same dimension that do not exist with one another.	Update will fail. The cube space will not contain the referenced cell.
Update includes a measure sourced to a measure of an unsigned type.	Update will fail. Increments require that the measure be able to take a negative value.
Update includes a measure that aggregates other than sum.	An error is raised.
Update was tried on a subcube.	An error is raised.

Affect of Cube Changes

The following changes will not have an effect on a writeback:

- Processing of a cube, the cube's measure groups, or the cube's dimensions.
- Adding attributes to any dimension.
- Adding a new dimension.
- Deleting a dimension that does not include the writeback.
- Adding, modifying, or removing a hierarchy.
- Adding a new measure.

The following changes cannot be made without removing the writeback data:

- Deleting an attribute, or its attribute hierarchy, if the attribute is included in the writeback. This includes explicitly removing the attribute, or its attribute hierarchy, or removing the attribute's parent dimension.
- Deleting a measure included in the writeback.
- Adding an attribute without an (All) level to a dimension included in the writeback.
- Changing the dimension granularity for a dimension included in the writeback.

Using Variables and Parameters (MDX)

Article • 06/27/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

In Microsoft SQL Server SQL Server Analysis Services, you can parameterize a Multidimensional Expressions (MDX) statement. A parameterized statement lets you create generic statements that can be customized at runtime.

In creating a parameterized statement, you identify the parameter name by prefixing the name with the at sign (@). For example, @Year would be a valid parameter name

MDX supports only parameters for literal or scalar values. To create a parameter that references a member, set, or tuple, you would have to use a function such as [StrToMember](#) or [StrToSet](#).

In the following XML for Analysis (XMLA) example, the @CountryName parameter will contain the country/region for which customer data is retrieved:

```
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
  <Body>
    <Execute xmlns="urn:schemas-microsoft-com:xml-analysis">
      <Command>
        <Statement>
          select [Measures].members on 0,
                 Filter(Customer.[Customer Geography].Country.members,
                        Customer.[Customer Geography].CurrentMember.Name =
                        @CountryName) on 1
          from [Adventure Works]
        </Statement>
      </Command>
      <Properties />
      <Parameters>
        <Parameter>
          <Name>CountryName</Name>
          <Value>'United Kingdom'</Value>
        </Parameter>
      </Parameters>
    </Execute>
  </Body>
</Envelope>
```

To use this functionality with OLE DB, you would use the **ICommandWithParameters** interface. To use this functionality with ADOMD.Net, you would use the

`AdomdCommand.Parameters` collection.

MDX Scripting Fundamentals (Analysis Services)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

In Microsoft SQL Server SQL Server Analysis Services, a Multidimensional Expressions (MDX) script is made up of one or more MDX expressions or statements that populate a cube with calculations.

An MDX script defines the calculation process for a cube. An MDX script is also considered part of the cube itself. Therefore, changing an MDX script associated with a cube immediately changes the calculation process for the cube.

To create MDX scripts, you can use Cube Designer in the SQL Server Data Tools. For more information, see [Define Assignments and Other Script Commands](#) and [Introduction to MDX Scripting in Microsoft SQL Server 2005](#).

For performance issues related to MDX queries and calculations, see the MDX optimization section in the [SQL Server Analysis Services Performance Guide](#).

In This Section

The Basic MDX Script (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

A Multidimensional Expressions (MDX) script defines the calculation process for a cube in Microsoft SQL Server SQL Server Analysis Services. There are two types of MDX scripts:

The default MDX script

At the time that you create a cube, SQL Server Analysis Services creates a default MDX script for that cube. This script defines a calculation pass for the whole cube.

User-defined MDX script

After you have created a cube, you can add user-defined MDX scripts that extend the calculation capabilities of the cube.

The Default MDX Script

The default MDX script that SQL Server Analysis Services creates when you define a cube contains a single CALCULATE statement. This single CALCULATE statement is at the beginning of the default MDX script, and indicates that the entire cube should be calculated during the first calculation pass.

The default MDX script also contains the script commands that create named sets, assignments, and calculated members created in Cube Designer:

- SQL Server Analysis Services directly adds script commands to the default MDX script.
- For each named set in the cube, a corresponding CREATE SET statement exists in the default MDX script.
- For each calculated member defined in the cube, a corresponding CREATE MEMBER statement exists in the default MDX script.

You can control the order of script commands, named sets, and calculated members in the default MDX script by using the **Calculations** tab of Cube Designer. For more information on defining calculations stored in the default MDX script, see [Calculations in Multidimensional Models](#).

If there is no MDX script associated with a cube, the cube assumes the default MDX script. A cube needs to be associated with at least one MDX script because a cube relies on the MDX script to determine calculation behavior. In other words, a cube that was not associated with an MDX script or was associated with an empty MDX script could not and would not be able to calculate any cells. If you programmatically create cubes, either by using Analysis Services Scripting Language (ASSL) commands or by using Analysis Management Objects (AMO), it is recommended that you create a default MDX script containing a single CALCULATE statement for the cube.

MDX Script Content

An MDX script can contain the following statements and expressions:

All MDX scripting statements

In MDX scripts, MDX scripting statements control the context and scope of calculations, and manage the behavior of other statements in the MDX script. This category includes the following statements:

- [CALCULATE](#)
- [FREEZE](#)
- [SCOPE](#)

For more information on MDX scripting statements, see [MDX Scripting Statements \(MDX\)](#).

[CREATE MEMBER](#)

The CREATE MEMBER statement creates calculated members. For more information about how to create calculated members, see [Building Calculated Members in MDX \(MDX\)](#).

[CREATE SET](#)

The CREATE SET statement creates named sets. For more information about how to create names sets, see [Building Named Sets in MDX \(MDX\)](#).

Conditional statements

Conditional statements add conditional logic to MDX scripts. This category includes the [CASE](#) and [IF](#) statements.

Assignment expressions

An assignment expression assigns an expression, such as a value, to a constrained subcube. A constrained subcube expression is a collection of constrained set

expressions that define the "edges" of a subcube within an MDX script. The following codes shows the syntax for a constrained subcube expression:

```
<Constrained subcube> ::= (
    ( <Constrained set> [<Crossjoin operator> <Constrained set>...] |
    <ROOT function> |
    <TREE function> |
    LEAVES() |
    * ) [, <Constrained subcube>...]
<Constrained set> ::= 
    <Natural hierarchy>.MEMBERS |
    <Natural hierarchy>.LEVEL(<numeric expression>).MEMBERS |
    { <Natural hierarchy member> } |
    DESCENDANTS( <Natural hierarchy member>, <Level expression>, ( SELF |
    AFTER | SELF_AND_AFTER ) ) |
    DESCENDANTS( <Natural hierarchy member>, , LEAVES )
<Natural hierarchy> ::= <Hierarchy identifier>
<Natural hierarchy member> ::= <Natural hierarchy>.<identifier>[.
    <identifier>...]
```

Managing Scope and Context (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

In Microsoft SQL Server SQL Server Analysis Services, a Multidimensional Expressions (MDX) script can apply to the entire cube, or to specific portions of the cube, at specific points within the execution of the script. The MDX script can take a layered approach to calculations within a cube through the use of calculation passes.

Note

For more information on how calculation passes can affect calculations, see [Understanding Pass Order and Solve Order \(MDX\)](#).

To control the calculation pass, scope, and context within an MDX script, you specifically use the CALCULATE statement, the **This** function, and the SCOPE statement.

Using the CALCULATE Statement

The CALCULATE statement populates each cell in the cube with aggregated data. For example, the default MDX script has a single CALCULATE statement at the beginning of the script.

For more information on the syntax of the CALCULATE statement, see [CALCULATE Statement \(MDX\)](#).

Note

If the script contains a SCOPE statement that contains a CALCULATE statement, MDX evaluates the CALCULATE statement within the context of the subcube defined by the SCOPE statement, not against the whole cube.

Using the This Function

The **This** function lets you retrieve the current subcube within an MDX script. You can use the **This** function to quickly set the value of cells within the current subcube to an MDX expression. You often use the **This** function in conjunction with the SCOPE

statement to change the contents of a specific subcube during a specific calculation pass.

① Note

If the script contains a SCOPE statement that contains a **This** function, MDX evaluates the **This** function within the context of the subcube defined by the SCOPE statement, not against the whole cube.

This Function Example

The following MDX script command example uses the **This** function to increase the value of the Amount measure, in the Finance measure group of the Adventure Works DW Multidimensional 2012 sample cube, to 10% higher for the children of the Redmond member in the Customer dimension:

```
/* This SCOPE statement defines the current subcube */
SCOPE([Customer].&[Redmond].MEMBERS,
      [Measures].[Amount], *);
      /* This expression sets the value of the Amount measure */
      THIS = [Measures].[Amount] * 1.1;
END SCOPE;
```

For more information on the syntax of the **This** function, see [This \(MDX\)](#).

Using the SCOPE Statement

The SCOPE statement defines the current subcube that contains, and specifies the scope of, other MDX expressions and statements within an MDX script. MDX evaluates this other MDX expressions and statements, including the **This** function and the CALCULATE statement, within the context of the subcube.

A SCOPE statement is dynamic, but not iterative in nature. The statements contained within a SCOPE statement run once, but the subcube itself can be dynamically determined. For example, you have a cube named SampleCube. Against the SampleCube cube, you apply the following SCOPE statement to define a subcube that defines the context as the ALLMEMBERS within the Measures dimension:

```
SCOPE([Measures].ALLMEMBERS);
```

```
THIS = [Measures].ALLMEMBERS.COUNT;
```

```
END SCOPE;
```

The statements and expressions within this SCOPE statement run once.

Now, a business user runs the following MDX query that contains one measure, named ExistingMeasure, against the SampleCube cube:

```
WITH MEMBER [Measures].[NewMeasure] AS '1'
```

```
SELECT
```

```
[Measures].ALLMEMBERS ON COLUMNS,
```

```
[Customer].DEFAULTMEMBER ON ROWS
```

```
FROM
```

```
[SampleCube]
```

The cellset returned from the query resembles the output shown in the following table.

[\[+\] Expand table](#)

	[ExistingMeasure]	[NewMeasure]
[Customer].[All]	2	2

Looking at the returned cellset, notice how the ExistingMeasure value, included in the SCOPE statement within the MDX script, is dynamically updated after the measure NewMeasure was defined.

A SCOPE statement can be nested within another SCOPE statement. However, as the SCOPE statement is not iterative, the primary purpose for nesting SCOPE statements is to further subdivide a subcube for special treatment.

SCOPE Statement Example

The following MDX script example uses a SCOPE statement to sets the value of the Amount measure, in the Finance measure group of the Adventure Works DW Multidimensional 2012 sample cube, to 10% higher for the children of the Redmond member in the Customer dimension. However, another SCOPE statement changes the subcube to include the Amount measure for the children of the 2002 calendar year.

Finally, the Amount measure is then aggregated only for that subcube, leaving the aggregated values for the Amount measure in other calendar years unchanged.

```
/* Calculate the entire cube first. */
CALCULATE;
/* This SCOPE statement defines the current subcube */
SCOPE([Customer].&[Redmond].MEMBERS,
      [Measures].[Amount], *);
      /* This expression sets the value of the Amount measure */
      THIS = [Measures].[Amount] * 1.1;
END SCOPE;
```

For more information on the syntax of the SCOPE statement, see [SCOPE Statement \(MDX\)](#).

Error Handling (MDX)

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services 
Fabric/Power BI Premium

Each cube can control how errors within a Multidimensional Expressions (MDX) script are handled. Error handling is done through the `ScriptErrorHandlingMode` enumerator. The possible values for this enumerator are:

IgnoreNone

Causes the server to raise an error when Microsoft SQL Server SQL Server Analysis Services finds any error in the MDX script.

IgnoreAll

Causes the server to ignore all commands in the MDX script that contain an error, including syntax errors, name resolution errors, and more.

Data Mining Programming

Article • 10/31/2023

Applies to:  SQL Server 2019 and earlier Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Important

Data mining was deprecated in SQL Server 2017 Analysis Services and now discontinued in SQL Server 2022 Analysis Services. Documentation is not updated for deprecated and discontinued features. To learn more, see [Analysis Services backward compatibility](#).

If you find that the built-in tools and viewers in SQL Server Analysis Services do not meet your requirements, you can extend the power of SQL Server Analysis Services by coding your own extensions. In this approach, you have two options:

- **XMLA**

SQL Server Analysis Services supports XML for Analysis (XMLA) as a protocol for communication with client applications. Additional commands are supported by SQL Server Analysis Services that extend the XML for Analysis specification.

Because SQL Server Analysis Services uses XMLA for data definition, data manipulation, and data control support, you can create mining structures and mining models by using the visual tools provided by SQL Server Data Tools, and then extend the data mining objects that you have created by using Data Mining Extensions (DMX) and Analysis Services Scripting Language (ASSL) scripts.

You can create and modify data mining objects entirely in XMLA scripts, and run prediction queries against the models programmatically from your own applications.

- **Analysis Management Objects (AMO)**

SQL Server Analysis Services also provides a complete framework that enables third-party data mining providers to integrate the data mining objects into SQL Server Analysis Services.

You can create mining structures and mining models by using AMO. See the following samples in CodePlex:

- AMO Browser

Connects to the SSAS instance you specify and lists all server objects and their properties, including mining structure and mining models.

- AMO Simple Sample

The AS Simple Sample covers programmatic access to most major objects, and demonstrates metadata browsing, and access to the values in objects.

The sample also demonstrates how to create and process a data mining structure and model, as well as browse an existing data mining model.

- DMX

You can use DMX to encapsulate command statements, prediction queries, and metadata queries and return results in a tabular format, assuming you have created a connection to an SQL Server Analysis Services server.

In This Section

[OLE DB for Data Mining](#)

Describes additions to the specification to support data mining and multidimensional data: new schema rowsets and columns, Data Mining Extensions (DMX) language for creating and managing mining structures.

Tabular Object Model (TOM)

Article • 11/10/2023

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

The Tabular Object Model (TOM) is an extension of the Analysis Management Object (AMO) client library, created to support programming scenarios for tabular models created at compatibility level 1200 and higher. As with AMO, TOM provides a programmatic way to handle administrative functions like creating models, importing and refreshing data, and assigning roles and permissions.

TOM exposes native tabular metadata, such as **model**, **tables**, **columns**, and **relationships** objects. A high-level view of the object model tree, provided below, illustrates how the component parts are related.

Because TOM is an extension of AMO, all classes representing new tabular objects are implemented in a new **Microsoft.AnalysisServices.Tabular.dll** assembly. General-purpose classes of AMO were moved to **Microsoft.AnalysisServices.Core** assembly. Your code will need to reference both assemblies. See [Install, distribute, and reference the Tabular Object Model \(Microsoft.AnalysisServices.Tabular\)](#) for details.

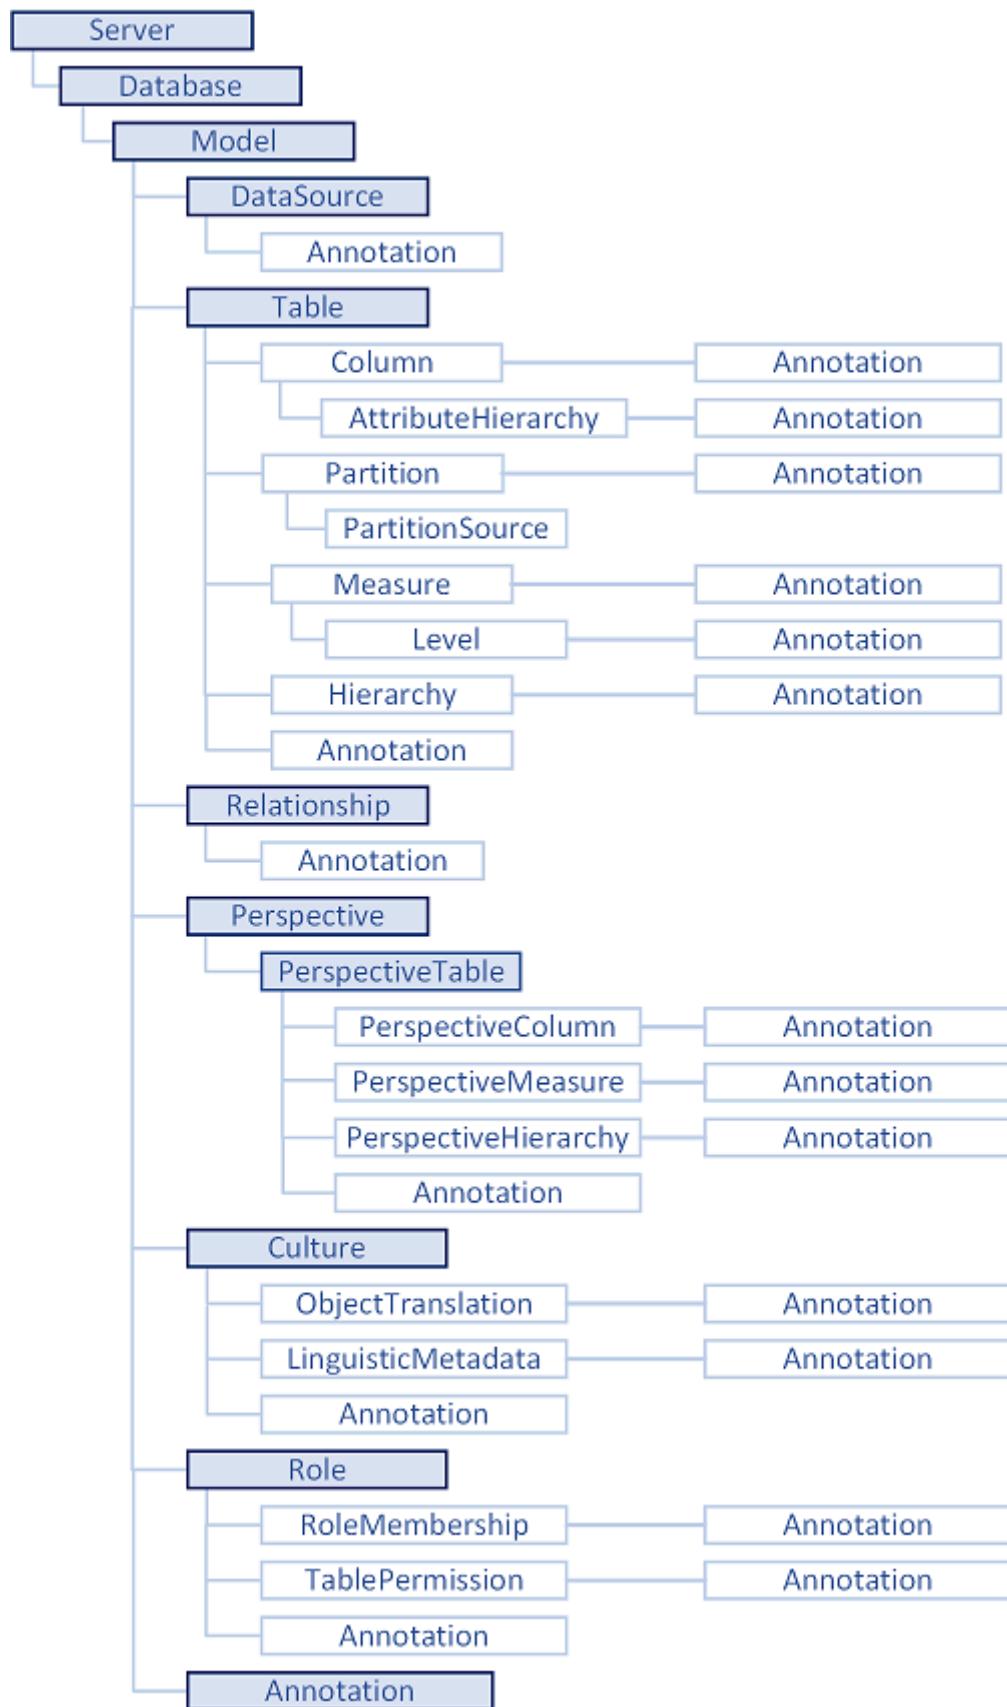

The API is available for managed .NET code. To learn more about specific AMO/TOM classes, see [Microsoft.AnalysisServices Namespace reference](#). To review the full list of programming options for tabular models, including script and query language support, see [Tabular Model Programming for Compatibility Level 1200](#).

Tabular object model hierarchy

From a logical perspective, all tabular objects form a tree, the root of which is a **Model**, descended from **Database**. **Server** and **Database** are not considered tabular because these objects can also represent a multidimensional database hosted on a server running in Multidimensional mode, or a tabular model at a lower compatibility level that does not use tabular metadata for object definitions.

With the exception of **AttributeHierarchy**, **KPI**, and **LinguisticMetadata**, each child object can be a member of a collection. For example, the **Model** object contains a collection of **Table** objects (via the **Tables** property), with each **Table** object containing a collection of **Column** objects, and so on.

The lowest level descendant of any parent object in this hierarchy is an **Annotation** object that can be used to optionally extend the schema as long as you provide the code to handle it.

TOM and other related technologies

TOM is built on top of the AMO infrastructure, which also accommodates multidimensional and tabular databases at compatibility levels below 1200. This has some practical implications. When you manage objects not specified in tabular metadata (such as a **Server** or **Database**), you need to leverage parts of the existing AMO stack that describe those objects. Along with the legacy API is the concept of major and minor objects that provide granular descriptions of object state as discovered from the server, or when saved to the server. The **MajorObject** class under `Microsoft.AnalysisServices` namespace exposes methods for **Refresh** and **Update**. Minor objects are only refresh or saved via the major object that contains them.

In contrast, when you manage objects that are part of tabular metadata, such as **Model** or **Table**, you leverage a completely new tabular stack. Within this stack, updates are fine-grained, which means every metadata object, derived from the **MetadataObject** class under the `Microsoft.AnalysisServices.Tabular` namespace, can be individually saved to the server. Typically, you would discover the entire **Model**. You then make changes to individual metadata objects under it, such as **Table** or **Column**. You then call **Model.SaveChanges()** method which understands changes made by you at fine-grained level, sending commands to the server to update only those objects that changed.

TOM and XMLA

On the wire, TOM uses the XMLA protocol to communicate with the server and to manage objects. When managing non-tabular objects, TOM uses ASSL, the Analysis Services Scripting Language extension of XMLA. When managing tabular objects, TOM uses the MS-SSAS-T tabular protocol, also an extension of XMLA. To learn more, see [MS-SSAS-T SQL Server Analysis Services Tabular protocol documentation](#).

TOM and JSON

Tabular metadata, which is structured as JSON documents, has a new command and object model definition syntax via the Tabular Model Scripting Language (TMSL). The scripting language uses JSON for the body of requests and responses.

Although both TMSL and TOM expose the same objects, **Table**, **Column** and so forth, and the same operations, **Create**, **Delete**, **Refresh**, TOM does not use TMSL on the wire. TOM uses the MS-SSAS-T tabular protocol instead, as previously noted.

As a user, you can choose whether to manage tabular databases through the TOM library from your C# program or PowerShell script, or through TMSL script executed through PowerShell, SQL Server Management Studio (SSMS), or a SQL Server Agent Job.

The decision to use one or the other will come down to the specifics of your requirements. The TOM library provides richer functionality compared to TMSL. Specifically, whereas TMSL only offers coarse-grained operations at the database, table, partition, or role level, TOM allows operations at a much finer grain. To generate or update models programmatically, you will need the full extent of the API in the TOM library.

Using TOM with Power BI

Power BI Premium, Premium Per User, and Power BI Embedded workspaces support open-platform connectivity through the XMLA endpoint. With the XMLA endpoint, custom tools, script, and automated processes can be used for data modeling and to perform workspace and semantic model administrative tasks.

Before creating a .Net application using TOM to work with Power BI semantic models, be sure to read [Semantic model connectivity with the XMLA endpoint](#) in the Power BI documentation. This article describes how to enable the XMLA endpoint for read-write access, get a workspace connection URL, and other important aspects for semantic model management with custom apps, external tools, and scripts.

To learn more about using the Tabular Object Model for semantic model administration and management, see [Programming Power BI semantic models \(TOM\)](#).

Connect to an existing tabular server and database

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Analysis Services Management Objects (AMO) includes several namespaces that can be used to set up a server connection. This article explains how to establish a server connection using the **Microsoft.AnalysisServices.Tabular** namespace for models and databases created at 1200 or higher compatibility level .

To connect to a server, your code must instantiate a Server object and then call the Connect method on it. Once connected, properties of the Server object will reflect the settings of the current server instance.

The following classes can be used for top-level connections:

- Microsoft.AnalysisServices.Server
- Microsoft.AnalysisServices.Database
- Microsoft.AnalysisServices.Tabular.Server
- Microsoft.AnalysisServices.Tabular.Database

As you can see, two namespaces provide connectivity to server and database objects: the original Microsoft.AnalysisServices namespace for AMO, and the new Microsoft.AnalysisServices.Tabular namespace for TOM.

Why two namespaces for the same operations? The answer lies downstream, at the database and model level, where the object hierarchy becomes mode-specific and the model tree is composed of either multidimensional or tabular metadata. To make calls in the model tree, the Server or Database object is provided for both model types.

Note

The metadata used for model definition and operations is completely different for the two modes. By separating the data definition language (DDL) into two separate namespaces, the development experience is simplified through the presentation of only the API needed for a specific model type.

Although the DDL differs, connections to a server are the same across all modes, versions, and editions. Supporting a server and database connection through either

namespace allows you to write generic tools or script that connect to any server instance or database, without having to know what type of model is hosted on the server. This flexibility explains the dependencies among the assemblies. In order to make calls below the Database level (for example, on a model within a Tabular 1200 database, or on a Cube, Dimension, or MeasureGroup within a Multidimensional or Tabular 1050-1103 database), AMO has a dependency on TOM.

In contrast, TOM does not have dependency on AMO. Although TOM cannot be used to explore multidimensional metadata (Cubes), AMO can be used to explore both multidimensional and tabular metadata. For this reason, the first step in setting up your project requires adding references to *all* of the AMO assemblies. See [Install, reference and distribute the TOM client library](#) for details.

ⓘ Note

Server and database connections are based on legacy AMO classes that inherit from MajorObject. Although major and minor objects aren't used in a tabular model tree, the MajorObject class is visible as a base class for Server and Database objects, regardless of which API you use to set up the connection.

Code example: server connection

Below is a C# code sample that shows how to connect to a local on-premises Analysis Services instance and list its properties in a console window.

This example shows only some of the properties of a Server object, but there are more properties available, including ServerMode and DefaultCompatibilityLevel.

C#

```
using System;
using Microsoft.AnalysisServices.Tabular;

namespace TOMSamples
{
    class Program
    {
        static void Main(string[] args)
        {
            //
            // Connect to the local default instance of Analysis Services
            //
            string ConnectionString = "DataSource=localhost";
```

```

// The using syntax ensures the correct use of the
// Microsoft.AnalysisServices.Tabular.Server object.
//
using (Server server = new Server())
{
    server.Connect(ConnectionString);

    Console.WriteLine("Connection established successfully.");
    Console.WriteLine();
    Console.ForegroundColor = ConsoleColor.Yellow;
    Console.WriteLine("Server name:\t\t{0}", server.Name);
    Console.WriteLine("Server product name:\t\t{0}",
server.ProductName);
    Console.WriteLine("Server product level:\t\t{0}",
server.ProductLevel);
    Console.WriteLine("Server version:\t\t\t{0}", server.Version);
    Console.ResetColor();
    Console.WriteLine();
}

Console.WriteLine("Press Enter to close this console window.");
Console.ReadLine();
}
}

```

When you run this program, the output shows properties on the Server object in a console window.

Authentication and authorization

A server or database connection to a server requires administrative permissions, used for read-write operations, and for passing through an impersonated connection request.

For Windows 2012 and later, delegation can be flowed across domains. In Analysis Services, delegation is used only for DirectQuery models; otherwise, connections are either direct or impersonated.

Next steps

After establishing a connection, a logical next step is to either list existing databases already on the server, or perhaps create a new empty database. The following links include code samples that demonstrate both of these basic tasks:

[Create and deploy an empty database](#)

List existing databases on a tabular server (AMO-TOM)

Article • 12/09/2022

Applies to: ✓ SQL Server 2016 and later Analysis Services ✓ Azure Analysis Services
✓ Fabric/Power BI Premium

When you have a **Server** object that is connected to a server instance, you can iterate over **Server.Databases** collection to list all databases hosted by the instance.

The **Server.Databases** collection contains one **Database** object for every database hosted on the server, regardless of server mode.

You can check the type of database through **Database.StorageEngineUsed** property.

Tabular 1200 and higher databases will return a non-null **Database.Model** property that gives access to all tabular metadata objects: Tables, Columns, Relationships, and so on.

For multidimensional or tabular 1103 and below, the **Database.Model** property will be null. In this case, non-tabular metadata will be available under multidimensional properties (such as **Database.Cubes** and **Database.Dimensions**), but those properties are only exposed by **Microsoft.AnalysisServices.Database** class (from AMO), not by **Microsoft.AnalysisServices.Tabular.Database** (for TOM). For more information about which Database class to use, see [Install, distribute, and reference the TOM client library](#).

Unless **Database.StorageEngineUsed** is set to **TabularMetadata**, you won't be able to use other classes in the tabular namespace to access or manipulate the model tree.

The following table summarizes expected behaviors when you connect to a server or database using a **Microsoft.AnalysisServices.Tabular** class on a server or database.

[] Expand table

mode	Database.model	Database.StorageEngineUsed
Tabular 1200 and later	Returns the name of the model	<code>StorageEngineUsed.TabularMetadata</code>
Tabular 1103, 1100, 1050	Returns null	<code>StorageEngineUsed.InMemory</code>
Multidimensional	Returns null	<code>StorageEngineUsed.Traditional</code>

Code example: List existing databases

The code below illustrates how to connect to the server and list databases hosted by server.

```
        }
    }
}
```

Get an item from a database

The following code snippet shows how to get a tabular or column from a database.

C#

```
var db = srv.Databases.GetByName("abc");

Column c1 = db.Model.Tables["foo"].Columns["bar"];
if (c1.ObjectType == ObjectType.Column) // always true

MetadataObject obj;

switch(obj.ObjectType)
{
    case ObjectType.Table:
        var t1 = (Table)obj;
        break;
}
```

Create and deploy an empty database (AMO-TOM)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

A common programming scenario for AMO-TOM is to generate databases and models on the fly. This article walks you through the steps of creating a database.

For tabular solutions, there is a one-to-one correspondence between a database and model, with one model per database. You can typically specify one or the other, and the engine will infer the missing object.

Creating and deploying a new database is a three-part task:

- Instantiate a **Database** object and set its properties, including a name.
- Add the **Database** object to a **Server.Databases** collection.
- Call the **Update** method on the **Database** object to save it to the **Server**.

Code example: create empty database

C#

```
using System;
using Microsoft.AnalysisServices;
using Microsoft.AnalysisServices.Tabular;

namespace TOMSamples
{
    class Program
    {
        static void Main(string[] args)
        {
            //
            // Connect to the local default instance of Analysis Services
            //
            string ConnectionString = "DataSource=localhost";

            //
            // The using syntax ensures the correct use of the
            // Microsoft.AnalysisServices.Tabular.Server object.
            //
            using (Server server = new Server())
```

```

    {
        server.Connect(ConnectionString);

        //
        // Generate a new database name and use GetNewName
        // to ensure the database name is unique.
        //
        string newDatabaseName =
            server.Databases.GetNewName("New Empty Database");

        //
        // Instantiate a new
        // Microsoft.AnalysisServices.Tabular.Database object.
        //
        var blankDatabase = new Database()
        {
            Name = newDatabaseName,
            ID = newDatabaseName,
            CompatibilityLevel = 1200,
            StorageEngineUsed = StorageEngineUsed.TabularMetadata,
        };
        //
        // Add the new database object to the server's
        // Databases connection and submit the changes
        // with full expansion to the server.
        //
        server.Databases.Add(blankDatabase);
        blankDatabase.Update(UpdateOptions.ExpandFull);

        Console.Write("Database ");
        Console.ForegroundColor = ConsoleColor.Yellow;
        Console.Write(blankDatabase.Name);
        Console.ResetColor();
        Console.WriteLine(" created successfully.");
        Console.WriteLine();
    }
    Console.WriteLine("Press Enter to close this console window.");
    Console.ReadLine();
}
}

```

Next steps

Once a database is created, you can add Model objects:

Add a data source to tabular model (AMO-TOM)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

The **DataSource** class in the Microsoft.AnalysisServices.Tabular namespace is an abstraction of a tabular model's data source that specifies the type and location of imported data during a data refresh operation.

You can add a data source to the tabular model by instantiating an object of a class derived from **DataSource**, and then add it to the **DataSources** collection of the **Model** object. To commit changes to the server, call either **Model.SaveChanges()** or **Database.Update(UpdateOptions.ExpandFull)**.

Tabular models support data import only from relational data sources, where the data provider exposes data in the form of tables and columns. As such, the tabular object model uses the **ProviderDataSource** class (derived from **DataSource**) to expose this capability.

Code example: add a data source

This example demonstrate how to instantiate a **ProviderDataSource** and add it to a data model.

C#

```
using System;
using Microsoft.AnalysisServices;
using Microsoft.AnalysisServices.Tabular;

namespace TOMSamples
{
    class Program
    {
        static void Main(string[] args)
        {
            //
            // Connect to the local default instance of Analysis Services
            //
            string ConnectionString = "DataSource=localhost";

            //
        }
    }
}
```

```

// The using syntax ensures the correct use of the
// Microsoft.AnalysisServices.Tabular.Server object.
//
using (Server server = new Server())
{
    server.Connect(ConnectionString);

    //
    // Generate a new database name and use GetNewName
    // to ensure the database name is unique.
    //
    string newDatabaseName =
        server.Databases.GetNewName("Database with a Data Source
Definition");

    //
    // Instantiate a new
    // Microsoft.AnalysisServices.Tabular.Database object.
    //
    var dbWithDataSource = new Database()
    {
        Name = newDatabaseName,
        ID = newDatabaseName,
        CompatibilityLevel = 1200,
        StorageEngineUsed = StorageEngineUsed.TabularMetadata,
    };

    //
    // Add a Microsoft.AnalysisServices.Tabular.Model object to
the
        // database, which acts as a root for all other Tabular
metadata objects.
    //
    dbWithDataSource.Model = new Model()
    {
        Name = "Tabular Data Model",
        Description = "A Tabular data model at the 1200
compatibility level."
    };

    //
    // Add a
Microsoft.AnalysisServices.Tabular.ProviderDataSource object
        // to the data Model object created in the previous step.
The connection
        // string of the data source object in this example
        // points to an instance of the AdventureWorks2014 SQL
Server database.
    //
    dbWithDataSource.Model.DataSources.Add(new
ProviderDataSource()
    {
        Name = "SQL Server Data Source Example",
        Description = "A data source definition that uses
explicit Windows credentials for authentication against SQL Server.",

```

```

        ConnectionString = "Provider=SQLNCLI11;Data
Source=localhost;Initial Catalog=AdventureWorks2014;Integrated
Security=SSPI;Persist Security Info=false",
        ImpersonationMode =
Microsoft.AnalysisServices.Tabular.ImpersonationMode.ImpersonateAccount,
        Account = @"\.\Administrator",
        Password = "P@ssw0rd",
    });

    //
// Add the new database object to the server's
// Databases connection and submit the changes
// with full expansion to the server.
//
server.Databases.Add(dbWithDataSource);
dbWithDataSource.Update(UpdateOptions.ExpandFull);

Console.Write("Database ");
Console.ForegroundColor = ConsoleColor.Yellow;
Console.Write(dbWithDataSource.Name);
Console.ResetColor();
Console.WriteLine(" created successfully.");
Console.WriteLine("The data model includes the following
data source definitions:");
Console.ForegroundColor = ConsoleColor.Yellow;
foreach (DataSource ds in
dbWithDataSource.Model.DataSources)
{
    Console.WriteLine("\tData source name:\t\t{0}",
ds.Name);
    Console.WriteLine("\tData source description:\t{0}",
ds.Description);
}
Console.ResetColor();
Console.WriteLine();
}
Console.WriteLine("Press Enter to close this console window.");
Console.ReadLine();
}
}
}

```

Next step

Within a model, you'll need to set up data bindings that map source columns in the data source to destination columns in the model. You will also need to define the partitions, a minimum of one per table, that store the data. The following link shows you how: [Create tables, partitions, and columns](#)

Create Tables, Partitions, and Columns in a Tabular model

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

In a tabular model, a table consists of rows and columns. Rows are organized into partitions to support incremental data refresh. A tabular solution can support several types of tables, depending on where the data is coming from:

- Regular tables, where data originates from a relational data source, via the data provider.
- Pushed tables, where data is "pushed" to the table programmatically.
- Calculated tables, where data comes from a DAX expression that references another object within the model for its data.

In the code example below, we'll define a regular table.

Required elements

A table must have at least one partition. A regular table must also have at least one column defined.

Every partition must have a Source specifying the data's origin, but source can be set to null. Typically, the source is a query expression that defines a slice of data in the relevant database query language.

Code example: create a Table, Column, Partition

Tables are represented by Table class (in Microsoft.AnalysisServices.Tabular namespace).

In the example below, we'll define a regular table having one partition linked to a relational data source and a few regular columns. We will also submit the changes to the server and trigger a data refresh that brings the data into the model. This represents the most typical scenario when you want to load data from a SQL Server relational database into a Tabular solution.

C#

```
using System;
using Microsoft.AnalysisServices;
using Microsoft.AnalysisServices.Tabular;

namespace TOMSamples
{
    class Program
    {
        static void Main(string[] args)
        {
            //
            // Connect to the local default instance of Analysis Services
            //
            string ConnectionString = "DataSource=localhost";

            //
            // The using syntax ensures the correct use of the
            // Microsoft.AnalysisServices.Tabular.Server object.
            //
            using (Server server = new Server())
            {
                server.Connect(ConnectionString);

                //
                // Generate a new database name and use GetNewName
                // to ensure the database name is unique.
                //
                string newDatabaseName =
                    server.Databases.GetNewName("Database with a Table
Definition");

                //
                // Instantiate a new
                // Microsoft.AnalysisServices.Tabular.Database object.
                //
                var dbWithTable = new Database()
                {
                    Name = newDatabaseName,
                    ID = newDatabaseName,
                    CompatibilityLevel = 1200,
                    StorageEngineUsed = StorageEngineUsed.TabularMetadata,
                };

                //
                // Add a Microsoft.AnalysisServices.Tabular.Model object to
the
                // database, which acts as a root for all other Tabular
metadata objects.
                //
                dbWithTable.Model = new Model()
                {
                    Name = "Tabular Data Model",
                };
            }
        }
    }
}
```

```

        Description = "A Tabular data model at the 1200
compatibility level."
    };

    //
    // Add a
Microsoft.AnalysisServices.Tabular.ProviderDataSource object
        // to the data Model object created in the previous step.
The connection
        // string of the data source object in this example
        // points to an instance of the AdventureWorks2014 SQL
Server database.
    //
    string dataSourceName = "SQL Server Data Source Example";
dbWithTable.Model.DataSources.Add(new ProviderDataSource()
{
    Name = dataSourceName,
    Description = "A data source definition that uses
explicit Windows credentials for authentication against SQL Server.",
    ConnectionString = "Provider=SQLNCLI11;Data
Source=localhost;Initial Catalog=AdventureWorks2014;Integrated
Security=SSPI;Persist Security Info=false",
    ImpersonationMode =
Microsoft.AnalysisServices.Tabular.ImpersonationMode.ImpersonateAccount,
    Account = @"\Administrator",
    Password = "P@ssw0rd",
});

    //
    // Add a table called Individual Customers to the data model
    // with a partition that points to a [Sales].
[vIndividualCustomer] view
    // in the underlying data source.
    //
    dbWithTable.Model.Tables.Add(new Table()
{
    Name = dbWithTable.Model.Tables.GetNewName("Individual
Customers"),
    Description = "Individual customers (names and email
addresses) that purchase Adventure Works Cycles products online.",
    Partitions = {
        //
        // Create a single partition with a
QueryPartitionSource for a query
            // that imports all customer rows from the
underlying data source.
        //
        new Partition() {
            Name = "All Customers",
            Source = new QueryPartitionSource() {
                DataSource =
dbWithTable.Model.DataSources[dataSourceName],
                Query = @"SELECT      [FirstName]
,[MiddleName]
,[LastName]

```

```

                ,[PhoneNumber]
                ,[EmailAddress]
                ,[City]
            FROM [Sales].[vIndividualCustomer]",
        }
    }
},
Columns =
{
    //
    // DataColumn objects refer to regular table columns.
    // Each DataColumn object corresponds to a column in
the underlying data source query.
    //
    new DataColumn() {
        Name = "FirstName",
        DataType = DataType.String,
        SourceColumn = "FirstName",
    },
    new DataColumn() {
        Name = "MiddleName",
        DataType = DataType.String,
        SourceColumn = "MiddleName",
    },
    new DataColumn() {
        Name = "LastName",
        DataType = DataType.String,
        SourceColumn = "LastName",
    },
    new DataColumn() {
        Name = "PhoneNumber",
        DataType = DataType.String,
        SourceColumn = "PhoneNumber",
    },
    new DataColumn() {
        Name = "EmailAddress",
        DataType = DataType.String,
        SourceColumn = "EmailAddress",
    },
    new DataColumn() {
        Name = "City",
        DataType = DataType.String,
        SourceColumn = "City",
    },
},
});

//
// Add the new database object to the server's
// Databases connection and submit the changes
// with full expansion to the server.
//
server.Databases.Add(dbWithTable);

//

```

```

        // Request a full refresh to import the data from the data
        source and
            // and perform any necessary recalculations.
            // The refresh operation will be performed with the next
            // invocation of Model.SaveChanges() or
Database.Update(UpdateOptions.ExpandFull);

dbWithTable.Model.RequestRefresh(Microsoft.AnalysisServices.Tabular.RefreshT
ype.Full);
    dbWithTable.Update(UpdateOptions.ExpandFull);

    Console.WriteLine("Database ");
    Console.ForegroundColor = ConsoleColor.Yellow;
    Console.Write(dbWithTable.Name);
    Console.ResetColor();
    Console.WriteLine(" created successfully.");

    Console.WriteLine("The data model includes the following
table definitions:");
        Console.ForegroundColor = ConsoleColor.Yellow;
        foreach (Table tbl in dbWithTable.Model.Tables)
        {
            Console.WriteLine("\tTable name:\t{0}", tbl.Name);
            Console.WriteLine("\tbl description:\t{0}",
tbl.Description);
        }
        Console.ResetColor();
        Console.WriteLine();
    }
    Console.WriteLine("Press Enter to close this console window.");
    Console.ReadLine();
}
}
}

```

Partitions in a table

Partitions are represented by a **Partition** class (in Microsoft.AnalysisServices.Tabular namespace). The **Partition** class exposes a **Source** property of **PartitionSource** type, which provides an abstraction over the different approaches for ingesting data into partition. A **Partition** instance can have a **Source** property as null, indicating that data will be pushed into the partition by sending chunks of data to the Server as part of push data API exposed by Analysis Services. In SQL Server 2016, **PartitionSource** class has two derived classes that represent ways to bind data to a partition: **QueryPartitionSource** and **CalculatedPartitionSource**.

Columns in a table

Columns are represented by several classes derived from base **Column** class (in Microsoft.AnalysisServices.Tabular namespace):

- **DataColumn** (for regular columns in regular tables)
- **CalculatedColumn** (for columns backed by DAX expression)
- **CalculatedTableColumn** (for regular columns in calculated tables)
- **RowNumberColumn** (special type of column created by SSAS for every table).

Row numbers in a table

Every **Table** object on a server has a **RowNumberColumn** used for indexing purposes. You can't create or add it explicitly. The column is created automatically when you save or update the object:

- `db.SaveChanges`
- `db.Update(ExpandFull)`

When calling either method, the server will create row number column automatically, which will be visible as **RowNumberColumn** the table's **Columns** collection.

Calculated tables

Calculated tables are sourced from a DAX expression that re-purposes data from existing data structures in the model or from out-of-line bindings. To create a calculated table programmatically, do the following:

- Create a generic **Table**.
- Add a partition to it with Source of type **CalculatedPartitionSource**, where the source is a DAX expression. The partition's source is what differentiates a regular table from a calculated table.

When you save the changes to the server, the server will return the inferred list of **CalculatedTableColumns** (calculated tables are composed of calculated table columns), visible via the table's **Columns** collection.

Handling errors in the TOM API (AMO-TOM)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

A common practice for managed libraries like Analysis Services Management Objects (AMO) Tabular Object Model (TOM) is to use exceptions as a mechanism for reporting error conditions to the user.

When an error is detected in AMO-TOM, besides throwing few standard .NET exceptions like **ArgumentException** and **InvalidOperationException**, TOM also can throw several TOM-specific exceptions.

TOM exceptions are derived from [AmoException Class](#), covering both AMO and TOM-specific exceptions.

To illustrate exception handling in TOM, let's review one of the more common exceptions, which is [OperationException Class](#).

OperationException is thrown when a user initiates an operation on the Analysis Services server and the server fails to perform an operation, either because the action was illegal, or because of another internal or external error.

When thrown, **OperationException** object will contain a list of XMLA errors returned by the server.

Note that the server will not accept changes that are invalid. If this occurs, revert the **Model** tree back into the last known good state using the [UndoLocalChanges Method](#), correct the model, then resubmit.

Code Example: handle exceptions

```
C#  
  
try  
{  
    // Change the Model, for example create a table.  
    // ...  
    model.saveChanges();  
}  
catch(operationException ex)
```

```
{  
    foreach(XmlError err in ex.Results.OfType<XmlError>().Cast<XmlError>())  
    {  
        Console.WriteLine("Error returned from the server:" + err.Message);  
    }  
}
```

Next steps

Other relevant exceptions include the following:

- [TomInternalException Class](#)
- [TomValidationException Class](#)
- [JsonSerializationException class ↗](#)

Install, distribute, and reference the Tabular Object Model

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

This article describes how to download, reference, and redistribute Tabular Object Model (TOM), a C# library for creating and managing tabular models and databases in managed code.

TOM is an extension of the AMO client library (`Microsoft.AnalysisServices.dll`). To use TOM, the model and database must be at compatibility level 1200 or higher.

AMO-TOM Assemblies

AMO includes new Core, Tabular, and JSON assemblies. It also includes the original AMO assembly, `Microsoft.AnalysisServices.dll`, that has been part of Analysis Services since its first release. A restructured AMO offloads common classes to one assembly, and provides a logical division between tabular and multidimensional APIs through additional assemblies.

The following table describes each assembly:

Expand table

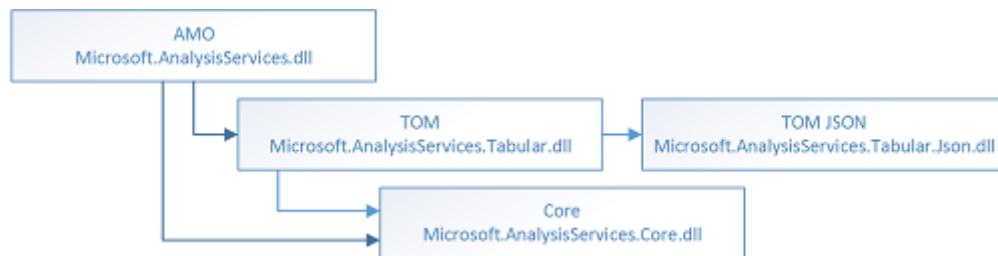

Assembly	Functionality	Important classes
Core <code>Microsoft.AnalysisServices.Core.dll</code>	Common to both tabular and multidimensional databases. Provides exception handling, generic connections to a server instance and database, and access to common properties and methods for Server and Database objects.	Core Server Core Database AmoException
TOM <code>Microsoft.AnalysisServices.Tabular.dll</code> , version 13.0.1601.5 or later.	Create and manage tabular metadata objects.	TOM Server TOM Database Model Table

Assembly	Functionality	Important classes
		Column Relationship
AMO Microsoft.AnalysisServices.dll	Create and manage multidimensional metadata objects, including tabular 1050-1103 databases.	AMO Server AMO Database Cube Dimension MeasureGroup
Json Microsoft.AnalysisServices.Tabular.Json.dll	A helper DLL that wraps the Newtonsoft.Json.dll (JSON.NET) to control updates, removing the risk of introducing functional changes to JSON serialization in server workloads. This DLL exists as a dependency in TOM and is not intended to be used directly in your code.	None.

Understanding assembly dependencies

To program against AMO, your solution must include references to dependent DLLs. Both AMO and TOM depend on Core because it provides base classes.

AMO depends on TOM because some classes in AMO reference classes from TOM. For example, the AMO Database object has a property Model of type Model, implemented in the TOM dll.

You can't distribute Microsoft.AnalysisServices.dll without Microsoft.AnalysisServices.Tabular.dll, but you can reference their respective namespaces without the other.

Choosing which namespace to use in code

In the object hierarchy, any object below Database is either a tabular metadata construction via the Model object, or a multidimensional metadata construction via a Cube, Dimension, or MeasureGroup object. For high-level operations at the Server, Database, Role, or Trace level, the choice of which namespace to reference will depend on the workloads your code needs to support.

- Use Tabular.Server or Tabular.Database if your solution is compatibility level 1200 or higher, and the Database object you work with must provide access to Model, Table, Columns, and other objects expressed as Tabular metadata constructions.
- Use AnalysisServices.Server or AnalysisServices.Database if downstream code references Multidimensional objects such as Cubes, DataSources, DataSourceViews, and Dimensions.

You'll need both namespaces for tools and applications supporting a mix of databases and model types.

Referencing the Core namespace in your code is unnecessary; the classes in Core are base classes created for the purpose of providing common properties, like Name and Description, for major objects.

Download and install AMO

1. Go to [Client libraries](#).
2. Select and download AMO by using Windows Installer or NuGet packages.

Add references

1. In **Solution Explorer > Add Reference > Browse**.
2. Go to **C:\Program Files\Microsoft SQL Server\140\SDK\Assemblies** and select:
 - Microsoft.AnalysisServices.Core
 - Microsoft.AnalysisServices.Tabular
 - Microsoft.AnalysisServices.Tabular.Json
3. Click **OK**. In **Solution Explorer**, confirm the assemblies exist in the References folder.
4. In your code page, add the `Microsoft.AnalysisServices.Tabular` namespace if databases and models are Tabular 1200 or higher compatibility level.

```
using Microsoft.AnalysisServices;
using Microsoft.AnalysisServices.Tabular;
```

When including namespaces that have classes in common for Server, Database, Role, and Trace objects, avoid ambiguous references by qualifying which namespace you want to use (for example, Microsoft.AnalysisServices.Tabular.Server instantiates a Server object using the Tabular namespace).

Redistribute AMO and TOM with your application

Redistribution of AMO and TOM is through the `sql_as_amo.msi` installation package or NuGet packages. If you are building a setup program for a client application that calls into AMO or TOM, add `sql_as_amo.msi` to your executable.

The package is self-contained and provides all assemblies required for calling AMO and TOM in your code. Other packages, such as `SQL_AS_OLEDB.msi` or `SQL_AS_ADOMD.msi`, are not specifically required for TOM programming scenarios.

Programming Power BI semantic models with the Tabular Object Model (TOM)

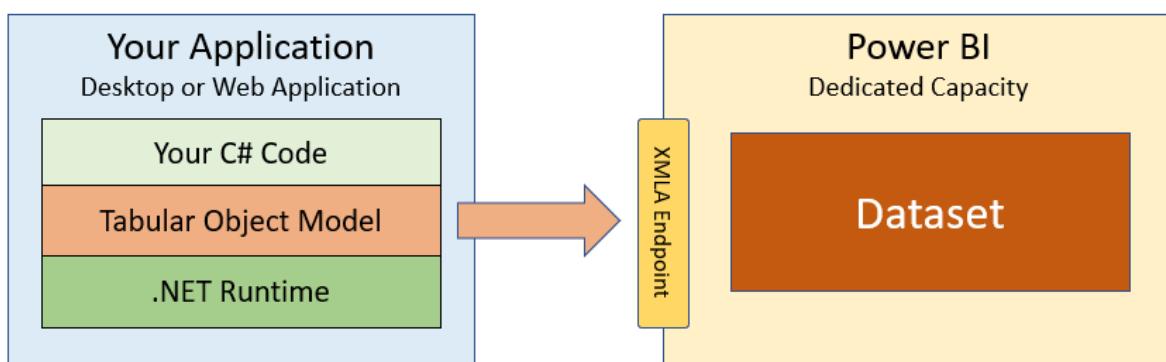

Article • 11/10/2023

Applies to: ✓ SQL Server 2016 and later Analysis Services ✓ Azure Analysis Services
✓ Fabric/Power BI Premium

This article was originally created by the Power BI Customer Advisory Team (CAT) for [Power BI Dev Camp](#), a collection of sessions, articles, and videos about advanced programming for Power BI.

Power BI Premium semantic models include the XMLA endpoint. The endpoint is significant to Power BI developers because it provides APIs to interact with the Analysis Services engine running in the Power BI Service and to directly program against Power BI models. A growing number of Power BI professionals have found that they can create, view and manage Power BI models by using pre-existing tools that use the XMLA protocol such as SQL Server Management Studio, Tabular Editor, and DAX Studio. As a .NET developer, you can now write C# code in a .NET application to create and modify models directly in the Power BI Service.

The Tabular Object Model (TOM) is a .NET library that provides an abstract layer on top of the XMLA endpoint. It allows developers to write code in terms of a intuitive programming model that includes classes like **Model**, **Table**, **Column**, and **Measure**. Behind the scenes, TOM translates the read and write operations in your code into HTTP requests executed against the XMLA endpoint.

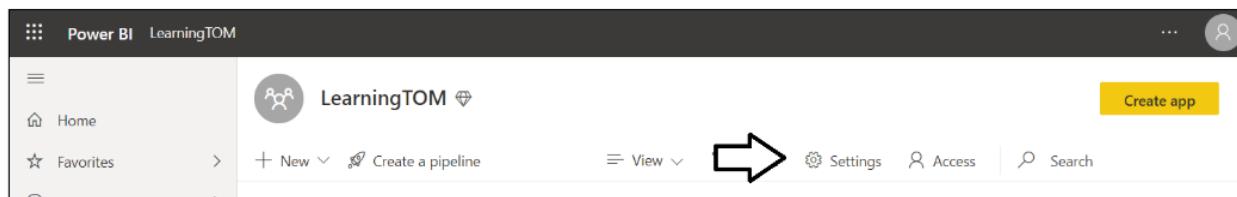

The focus of this article is getting started with TOM and demonstrating how to write the C# code required to create and modify models while they're running in the Power BI Service. However, TOM can also be used in scenarios that do not involve the XMLA endpoint, such as when programming against a local model running in Power BI.

Desktop. To learn more about using TOM with Power BI Desktop, see Power BI CAT member Phil Seamark's [blog series](#), and be sure watch the [How to program datasets using the Tabular Object Model \(TOM\)](#) video from the Power BI Dev Camp.

TOM represents a new and powerful API for Power BI developers that is separate and distinct from the Power BI REST APIs. While there is some overlap between these two APIs, each of these APIs includes a significant amount of functionality not included in the other. Furthermore, there are scenarios that require a developer to use both APIs together to implement a full solution.

Getting Started with the Tabular Object Model

The first thing you need to get before you can program with TOM is the URL for a workspace connection. The workspace connection URL references a specific workspace and is used to create a connection string that allows your code to connect to that Power BI workspace and the models running inside. Start by navigating to the **Settings** page of a Power BI workspace running in a dedicated capacity.

ⓘ Note

XMLA endpoint is supported for models running in a dedicated capacity only. It's not available for models running in a shared capacity. If working with models in a Power BI Premium per User capacity, you can connect as a user but you cannot connect as a service principal.

Once you navigate to the **Premium** tab of the **Settings** pane, copy the Workspace Connection URL to the clipboard.

The screenshot shows the 'Settings' page for a workspace named 'LearningTOM'. The 'Premium' tab is selected. Under 'Premium capacity', the switch is set to 'On' for 'P1 MVP - East US 2'. The 'Default storage format' is set to 'Small dataset storage format'. A large black arrow points to the 'Workspace Connection' section, which displays the URL 'powerbi://api.powerbi.com/v1.0/myorg/LearningTOM'.

The next step is to create a new .NET application in which you write the C# code that programs using TOM. You can create a Web application or a Desktop application using .NET 5, .NET Core 3.1, or older versions on the .NET Framework. In this article we create a simple C# console application using the [.NET 5 SDK](#).

Create a new console application

Begin by using the [.NET CLI](#) to create a new console application.

```
.NET CLI  
dotnet new console --name `
```

Add the Tabular Object Model NuGet package

After creating the console application, add the [Microsoft.AnalysisServices.AdomdClient.NetCore.retail.amd64](#) NuGet package which

contains the Tabular Object Model (TOM). You can install the package in a .NET 5 application by using the following .NET CLI:

```
.NET CLI
```

```
dotnet add package Microsoft.AnalysisServices.NetCore.retail.amd64
```

Add the connection string

When your project has the NuGet package with the TOM library installed, you can then create the traditional **Hello World** application with TOM. The application connects to a Power BI workspace by using the Workspace Connection URL, and then enumerates through the models in the workspace and displays their names in the console window.

```
.NET CLI
```

```
using System;
using Microsoft.AnalysisServices.Tabular;

class Program {
    static void Main() {

        // create the connect string
        string workspaceConnection =
"powerbi://api.powerbi.com/v1.0/myorg/LearningTOM";
        string connectionString = $"DataSource={workspaceConnection};";

        // connect to the Power BI workspace referenced in connect string
        Server server = new Server();
        server.Connect(connectionString);

        // enumerate through models in workspace to display their names
        foreach (Database database in server.Databases) {
            Console.WriteLine(database.Name);
        }
    }
}
```

In this example, the connection string contains the Workspace Connection URL but no information about the user. If you run the console application with this code, the application will begin to run and then you'll be prompted with a browser-based window to log in. If you log in with a user account that has permissions to access the workspace referenced by the Workspace Connection URL, the TOM library is able to acquire an access token, connect to the Power BI Service, and enumerate through the models in the workspace.

To learn more about connecting through the XMLA endpoint, see [Sematic model connectivity with the XMLA endpoint - Connecting to a Premium workspace](#).

Authenticating with user name and password

For development and testing scenarios where security is not as important, you can hard-code your user name and password, eliminating the need to log in interactively each time you run a program to test your code, as shown in the following code:

.NET CLI

```
string workspaceConnection =
"powerbi://api.powerbi.com/v1.0/myorg/YOUR_WORKSPACE";
string userId = "YOUR_USER_NAME";
string password = "YOUR_USER_PASSWORD";
string connectStringUser = $"DataSource={workspaceConnection};User ID=
{userId};Password={password}";"
server.Connect(connectStringUser);
```

Authenticating with a service principal

It's also quite easy to authenticate as a service principal instead of as a user. If you've created a Microsoft Entra application with an Application ID and an application secret, you can authenticate your code to run as the service principal for the Microsoft Entra application by using the following code sample:

.NET CLI

```
string workspaceConnection =
"powerbi://api.powerbi.com/v1.0/myorg/YOUR_WORKSPACE";
string tenantId = "YOUR_TENANT_ID";
string appId = "YOUR_APP_ID";
string appSecret = "YOUR_APP_SECRET";
string connectStringApp = $"DataSource={workspaceConnection};User ID=app:
{appId}@{tenantId};Password={appSecret}";"
server.Connect(connectStringApp);
```

To program with TOM and access a model as a service principal, you must configure a tenant-level Power BI setting in the Power BI Admin portal. The steps for configuring Power BI to support connecting as a service principal is described in [Embed Power BI content with service principal and an application secret](#).

Authenticating with a Microsoft Entra access token

TOM also provides flexibility when establishing a connection using a valid Microsoft Entra access token. If you have the developer skills to implement an authentication flow with Microsoft Entra ID and acquire access tokens, you can format your TOM connection string without a user name, but include the access token as the password instead, as shown in the following code sample:

.NET CLI

```
public static void ConnectToPowerBIAsUser() {
    string workspaceConnection =
    "powerbi://api.powerbi.com/v1.0/myorg/YOUR_WORKSPACE";
    string accessToken = TokenManager.GetAccessToken(); // you must implement
    GetAccessToken yourself
    string connectStringUser = $"DataSource={workspaceConnection};Password=
    {accessToken}";
    server.Connect(connectStringUser);
}
```

If you're acquiring a user-based access token to connect to a Power BI workspace with TOM, be sure to request the following delegated permissions when acquiring access token to ensure you have all the authoring permissions you need:

.NET CLI

```
public static readonly string[] XmlaScopes = new string[] {
    "https://analysis.windows.net/powerbi/api/Content.Create",
    "https://analysis.windows.net/powerbi/api/Dataset.ReadWrite.All",
    "https://analysis.windows.net/powerbi/api/Workspace.ReadWrite.All",
};
```

If you've been programming with the Power BI REST API, you might recognize familiar permissions such as **Content.Create**, **Dataset.ReadWrite.All** and **Workspace.ReadWrite.All**. An interesting observation is that TOM uses the same set of delegated permissions as the Power BI REST API defined within the scope of the Microsoft Entra resource ID of <https://analysis.windows.net/powerbi/api>.

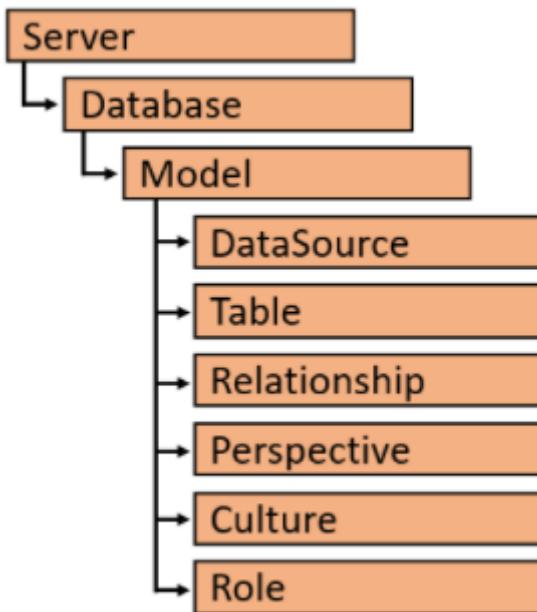

The fact that both the XMLA endpoint and the Power BI REST API share the same set of delegated permissions has its benefits. Access tokens can be used interchangeably between TOM and the Power BI REST API. Once you have acquired an access token to call into TOM to create a new model, you can use the same access token to call the Power BI REST API to set the data source credentials, as described later in this article.

One thing that tends to confuse Power BI programmers is that service principals do not use delegated permissions. Instead, when programming with TOM you configure access

for a service principal by adding it to the target workspace as a member in the role of Admin or Member.

Understanding server, database, and model objects

The object model in TOM is based on a hierarchy with the top-level **Server** object which contains a collection of **Database** objects. When programming with TOM in Power BI, the **Server** object represents a Power BI workspace and the **Database** object represents a Power BI model.

Each **Database** contains a **Model** object which provides read/write access to the data model. The **Model** contains collections for the elements of a data model including **DataSource**, **Table**, **Relationship**, **Perspective**, **Culture**, and **Role**.

As shown in the **Hello World** code, once you call **server.Connect**, you can easily discover what models exist inside a Power BI workspace by enumerating through the **Databases** collection of the **Server** object as shown in the following code:

.NET CLI

```
foreach (Database database in server.Databases) {  
    Console.WriteLine(database.Name);  
}
```

You can also use the **GetByName** method exposed by the **Databases** collection object to access a model by name, like this:

.NET CLI

```
Database database = server.Databases.GetByName("Wingtip Sales");
```

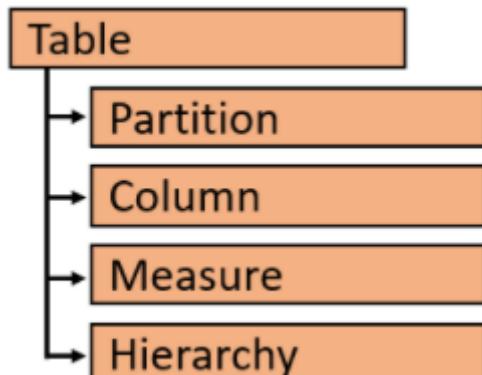

It's important to distinguish between a **Databaseobject** and its inner **Model** property. You can use **Database** object properties to discover model attributes such as **Name**, **ID**, **CompatibilityMode**, and **CompatibilityLevel**. There's also an **EstimatedSize** property which makes it possible to discover how big a model has grown. Other properties include **LastUpdate**, **LastProcessed**, and **LastSchemaUpdate** which allow you to determine when the underlying model was last refreshed and when the model schema was last updated.

.NET CLI

```
public static void GetDatabaseInfo(string DatabaseName) {  
    Database database = server.Databases.GetByName(DatabaseName);  
    Console.WriteLine("Name: " + database.Name);  
    Console.WriteLine("ID: " + database.ID);  
    Console.WriteLine("CompatibilityMode: " + database.CompatibilityMode);  
    Console.WriteLine("CompatibilityLevel: " + database.CompatibilityLevel);  
    Console.WriteLine("EstimatedSize: " + database.EstimatedSize);  
    Console.WriteLine("LastUpdated: " + database.LastUpdate);  
    Console.WriteLine("LastProcessed: " + database.LastProcessed);  
    Console.WriteLine("LastSchemaUpdate: " + database.LastSchemaUpdate);  
}
```

While the **Database** object has its own properties, it is the inner **Model** object of a **Database** object that provides you with the ability to read and write to a model's underlying data model. Here's a simple example of programming the database **Model** object to enumerate through its **Tables** collection and discover what tables are inside.

In the TOM object model, each **Table** object has collection objects for its partitions, columns, measures and hierarchies.

Once you've retrieved the **Model** object for a **Database**, you can access a specific table by name in the model by using the **Find** method of the **Tables** collection. Here's an example retrieving a table named **Sales**, and discovering its members by enumerating through the **Columns** collection and **Measures** collection:

.NET CLI

```
Model databaseModel = server.Databases.GetByName("Tom Demo").Model;

Table tableSales = databaseModel.Tables.Find("Sales");

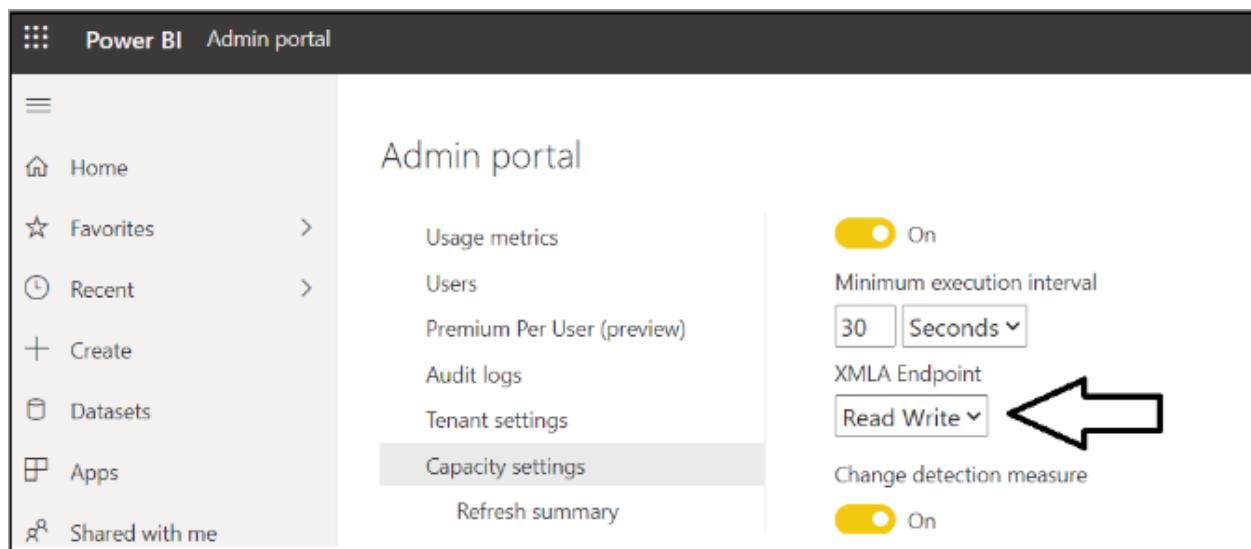

foreach (Column column in tableSales.Columns) {
    Console.WriteLine("Column: " + column.Name);
}

foreach (Measure measure in tableSales.Measures) {
    Console.WriteLine("Measure: " + measure.Name);
    Console.WriteLine(measure.Expression);
}
```

Modifying models with TOM

In the sections above, you've seen how to access a **Database** object and its **Model** object to inspect the data model of a model running in the Power BI Service. Now it's time to program our first model update with TOM by adding a measure to a table.

The capacity you're using must be [enabled for XMLA read-write](#). By default, the XMLA endpoint permissions setting is set to **Read**, so it must be explicitly set to **Read Write** by someone with **Capacity Admin** permissions. This setting can be viewed and updated in the **Capacity settings** page in the [Admin portal](#).

When the XMLA endpoint has been configured for read-write, you can then add a new measure named **Sales Revenue** to the **Sales** table, as shown in the following code:

.NET CLI

```
Model dataset = server.Databases.GetByName("Tom Demo Starter").Model;
Table tableSales = dataset.Tables.Find("Sales");
Measure salesRevenue = new Measure();
salesRevenue.Name = "Sales Revenue";
salesRevenue.Expression = "SUM(Sales[SalesAmount])";
salesRevenue.FormatString = "$#,##0.00";
tableSales.Measures.Add(salesRevenue);
dataset.SaveChanges();
```

Let's take a closer look at this code. First, you create a new **Measure** object using the C# **new** operator and provide values for the **Name**, **Expression**, and **FormatString**. You then add the new **Measure** object to the **Measures** collection of the target **Table** object by calling the **Add** method. Finally, call the **SaveChanges** method of the **Model** object to write your changes back to the model in the Power BI Service.

Keep in mind that updates to a model are batched in memory until you call **SaveChanges**. Imagine a scenario where you'd like to hide every column in a table. You can start by writing a **foreach** loop to enumerate through all the **Column** objects for a table and setting the **IsHidden** property for each **Column** object to true. After the **foreach** loop completes, you have several column updates that are batched in memory. But it's the final call to **SaveChanges** that push all the changes back to the Power BI Service in a batch, as shown below:

.NET CLI

```
Model dataset = server.Databases.GetByName("Tom Demo").Model;
Table tableSales = dataset.Tables.Find("Sales");

foreach (Column column in tableSales.Columns) {
    column.isHidden = true;
}

dataset.SaveChanges();
```

Let's say you want to update the **FormatString** property for an existing column. The **Columns** collection exposes a **Find** method to retrieve the target **Column** object. After that, it's just a matter of setting the **FormatString** property and calling **SaveChanges**, like this:

.NET CLI

```
Model dataset = server.Databases.GetByName("Tom Demo").Model;
Table tableSales = dataset.Tables.Find("Products");
Column columnListPrice = tableSales.Columns.Find("List Price");
columnListPrice.FormatString = "#,##0.00";
dataset.SaveChanges();
```

TOM's ability to dynamically discover what's inside a model provides opportunities to perform updates in a generic and sweeping fashion. Imagine a scenario in which you are managing a model which has lots of tables and tens or even hundreds of columns based on the **DateTime** datatype. You can update the **FormatString** property for each **DateTime** column in the entire model at the same by using the following:

.NET CLI

```
Database database = server.Databases.GetByName("Tom Demo Starter");
Model datasetModel = database.Model;

foreach (Table table in datasetModel.Tables) {
    foreach (Column column in table.Columns) {
        if(column.DataType == DataType.DateTime) {
            column.FormatString = "yyyy-MM-dd";
        }
    }
}

datasetModel.SaveChanges();
```

Refreshing models with TOM

Now let's perform a typical model maintenance operation. As you see in the following code, it's not very complicated to start a model refresh operation by using TOM:

.NET CLI

```
public static void RefreshDatabaseModel(string Name) {
    Database database = server.Databases.GetByName(Name);
    database.Model.RequestRefresh(RefreshType.DataOnly);
    database.Model.SaveChanges();
}
```

Just like with manual and scheduled model refresh, refreshes through the XMLA endpoint are shown in **Refresh history**, but with the label, **Via XMLA Endpoint**.

Refresh history

Scheduled	OneDrive		
On demand	7/14/2021, 12:17:07 PM	7/14/2021, 12:25:05 PM	Completed
Via XMLA Endpoint	7/14/2021, 11:32:49 AM	7/14/2021, 11:41:23 AM	Completed
On demand	7/14/2021, 11:18:38 AM	7/14/2021, 11:27:48 AM	Completed
On demand	7/14/2021, 10:55:10 AM	7/14/2021, 11:03:54 AM	Completed
On demand	7/14/2021, 9:21:54 AM	7/14/2021, 9:33:23 AM	Completed
Scheduled	7/14/2021, 7:04:01 AM	7/14/2021, 7:23:55 AM	Completed
On demand	7/13/2021, 10:15:28 PM	7/13/2021, 10:29:35 PM	Completed
On demand	7/13/2021, 6:13:34 PM	7/13/2021, 6:22:32 PM	Completed
On demand	7/13/2021, 4:21:05 PM	7/13/2021, 4:31:17 PM	Completed

Close

ⓘ Note

While TOM provides the ability to start a refresh operation, it cannot set *data source credentials* for a Power BI model. In order to refresh models with TOM, you must first set the data source credentials in **Semantic model settings** or by using the Power BI REST APIs.

Creating and cloning models

Imagine you have a requirement to create and clone Power BI models using code written in C#. Let's begin by writing a reusable function named **CreateDatabase** that creates a new **Database** object, like this:

C#

```
public static Database CreateDatabase(string DatabaseName) {

    string newDatabaseName = server.Databases.GetNewName(DatabaseName);
    var database = new Database() {
        Name = newDatabaseName,
        ID = newDatabaseName,
        CompatibilityLevel = 1520,
        StorageEngineUsed =
            Microsoft.AnalysisServices.StorageEngineUsed.TabularMetadata,
        Model = new Model() {
            Name = DatabaseName + "-Model",
            Description = "A Demo Tabular data model with 1520 compatibility
level."
        }
    };
}
```

```
        server.Databases.Add(database);
        database.Update(Microsoft.AnalysisServices.UpdateOptions.ExpandFull);
        return database;
    }
```

In this example, we'll start by using the `GetNewName` method of the `Databases` collection object to ensure our new model name is unique within the target workspace. After that, the `Database` object and its `Model` object can be created by using the C# `new` operator as shown in the code below. At the end, this method adds the new `Database` object to the `Databases` collection and calls the `database.Update` method.

If your goal is to copy an existing model instead of creating a new one, you can use the following `CopyDatabase` method to clone a Power BI model by creating a new empty model and then calling `CopyTo` on the `Model` object for the source model to copy the entire data model into the newly created model.

C#

```
public static Database CopyDatabase(string sourceDatabaseName, string
    DatabaseName) {
    Database sourceDatabase = server.Databases.GetByName(sourceDatabaseName);
    string newDatabaseName = server.Databases.GetNewName(DatabaseName);
    Database targetDatabase = CreateDatabase(newDatabaseName);
    sourceDatabase.Model.CopyTo(targetDatabase.Model);
    targetDatabase.Model.SaveChanges();
    targetDatabase.Model.RequestRefresh(RefreshType.Full);
    targetDatabase.Model.SaveChanges();
    return targetDatabase;
}
```

Creating a real-world model from scratch

OK, now imagine you've just created a new model from scratch and now you need to use TOM to compose a real-world data model by adding tables, columns, measures, hierarchies, and table relationships. Let's look at a code example that creates a new table that includes defined columns, adds a three-level dimensional hierarchy, and even supplies the M expression for the underlying table query:

C#

```
private static Table CreateProductsTable() {

    Table productsTable = new Table() {
        Name = "Products",
        Description = "Products table",
```

```

Partitions = {
    new Partition() {
        Name = "All Products",
        Mode = ModeType.Import,
        Source = new MPartitionSource() {
            // M code for query maintained in separate source file
            Expression = Properties.Resources.ProductQuery_m
        }
    },
    Columns = {
        new DataColumn() { Name = "ProductId", DataType = DataType.Int64,
SourceColumn = "ProductId", IsHidden = true },
        new DataColumn() { Name = "Product", DataType = DataType.String,
SourceColumn = "Product" },
        new DataColumn() { Name = "Description", DataType = DataType.String,
SourceColumn = "Description" },
        new DataColumn() { Name = "Category", DataType = DataType.String,
SourceColumn = "Category" },
        new DataColumn() { Name = "Subcategory", DataType = DataType.String,
SourceColumn = "Subcategory" },
        new DataColumn() { Name = "Product Image", DataType = DataType.String,
SourceColumn = "ProductImageUrl", DataCategory =
"ImageUrl" }
    }
};

productsTable.Hierarchies.Add(
    new Hierarchy() {
        Name = "Product Category",
        Levels = {
            new Level() { Ordinal=0, Name="Category",
Column=productsTable.Columns["Category"] },
            new Level() { Ordinal=1, Name="Subcategory",
Column=productsTable.Columns["Subcategory"] },
            new Level() { Ordinal=2, Name="Product",
Column=productsTable.Columns["Product"] }
        }
    });
}

return productsTable;
}

```

Once you've created a set of helper methods to create the tables, you can then compose them together to create a data model, like this:

C#

```

Model model = database.Model;
Table tableCustomers = CreateCustomersTable();
Table tableProducts = CreateProductsTable();
Table tableSales = CreateSalesTable();
Table tableCalendar = CreateCalendarTable();

```

```
model.Tables.Add(tableCustomers);
model.Tables.Add(tableProducts);
model.Tables.Add(tableSales);
model.Tables.Add(tableCalendar);
```

TOM exposes a **Relationships** collection on the **Model** object which allows you to define the relationships between the tables in your model. Here's the code required to create a **SingleColumnRelationship** object which establishes a *one-to-many* relationship between the **Products** table and the **Sales** table:

C#

```
model.Relationships.Add(new SingleColumnRelationship {
    Name = "Products to Sales",
    ToColumn = tableProducts.Columns["ProductId"],
    ToCardinality = RelationshipEndCardinality.One,
    FromColumn = tableSales.Columns["ProductId"],
    FromCardinality = RelationshipEndCardinality.Many
});
```

After you're done adding the tables and table relationship, save your work with a call to **model.SaveChanges**:

C#

```
model.SaveChanges();
```

At this point, after calling **SaveChanges**, you should be able to see the new model created in the Power BI Service and begin using it to create new reports.

The screenshot shows the Power BI desktop interface. On the left is a navigation bar with icons for Home, Favorites, Recent, and others. The main area contains a data grid titled 'Category' with columns for '2012' and '2013'. The grid lists various product categories like Action Figures, Arts and Crafts, Drawing, Painting, and Remote Control Vehicles, along with their sales figures for each year. To the right of the grid is the 'Fields' pane, which includes a search bar and sections for 'Visualizations' (with icons for different chart types), 'Rows' (listing Product Category, Category, Subcategory, and Product), 'Columns' (listing Year), and 'Values' (listing Sales Revenue). A 'Filter' icon is also present in the top right of the Fields pane.

ⓘ Important

Remember, you must specify data source credentials in Semantic model settings or through the Power BI REST API before you can refresh the model.

Sample project

The sample project with the C# code you've seen in this article is available [here](#). Now it's time for you to start programming with TOM and to find ways to leverage this powerful new API in the development of custom solutions for Power BI.

Use hot and cold table partitions to optimize very large Power BI data models

Article • 04/10/2024

This article describes how to use hot and cold table partitions to optimize very large data models. Partitions provide a way to divide a table's data into discrete subsets. Partitions are *not* directly exposed in the standard Power BI data modeling tools, but you can take advantage of advanced partitioning methods by configuring an incremental refresh policy in Power BI Desktop. Incremental refresh relies on partitions, as explained in [Incremental refresh and real-time data for datasets](#). However, configuring hot and cold table partitions goes beyond what an incremental refresh policy can accomplish and assumes familiarity with typical table partitioning schemes and XMLA-based tools.

Prerequisites

Due to the relative complexity of this partitioning technique, it's most suitable for advanced users with experience in the following areas:

1. Understanding table partitioning concepts, how import mode partitions, *DirectQuery* mode, and *Dual* mode work.
2. Knowledge of how to create hybrid tables using XMLA-based tools. Hybrid tables use one or more import-mode partitions and one *DirectQuery* partition.
3. Knowledge of the requirements of the DAX functions you can use to specify a `DataCoverageDefinition`. This is a new property for *DirectQuery* partitions to describe what data the *DirectQuery* partition of a hybrid table contains so that the Power BI engine can exclude this partition from query processing where appropriate. Excluding the *DirectQuery* partition can help to avoid unnecessary data source queries and improve the performance of DAX query processing.
4. Understanding the difference between regular and limited table relationships. For example, the RELATED function is useful if you want to define the data coverage of a facts table partition based on the values from a related date dimension table. Keep in mind that the facts table partition is a *DirectQuery* partition with a chance of a limited relationship to the date table over which the RELATED function can't fetch values. In this scenario, RELATED only works if the date dimension table is a

dual table. The date table has to be in *DirectQuery* or *Dual* mode. It can't be pure import.

Be aware that an incorrectly defined `DataCoverageDefinition` could lead to wrong results because Power BI might incorrectly exclude the *DirectQuery* partition from query processing. So, make sure you compare the results with and without the `DataCoverageDefinition` to ensure they add up.

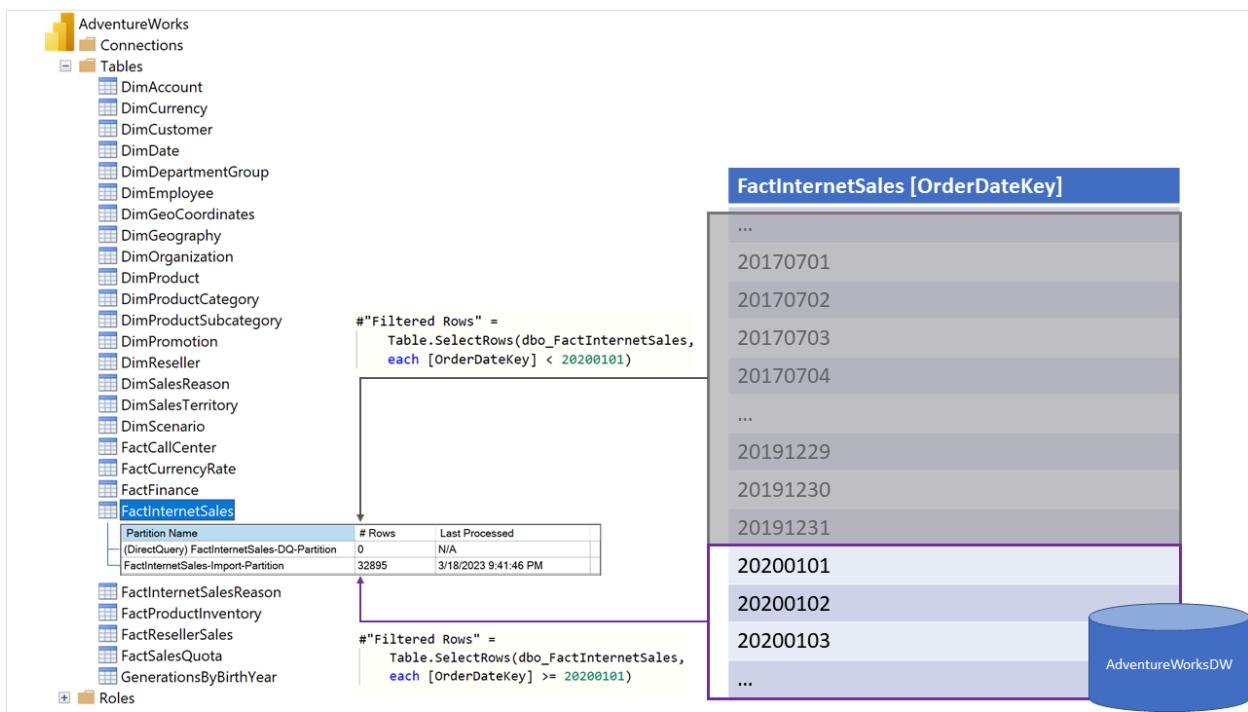

When to use hot and cold table partitions

Here's an example in which hot and cold partitions can help fine-tune a hybrid table for historic analysis. Assume you have a very large data source, accumulated over many years. The primary use is to analyze the most recent data from the last couple of years. Occasionally, you also want to analyze older data. Perhaps you noticed a recent sharp sales increase year over year. Did that ever happen before? Is it the highest sales spike since the beginning of sales tracking?

Without support for hot and cold partitions, this kind of historic analysis would require you to import all the historic data along with the more recent data into the facts table. At best, this is an inefficient use of resources as the primary analysis doesn't even use any of the older historic data. At worst, the data volume is so large that it can't even be imported in full. You either have to switch the data model to *DirectQuery* mode and accept a performance penalty in comparison to import mode, or you can build separate models and force your users to switch between reports. A hybrid table with hot and cold partitions gives you a better option.

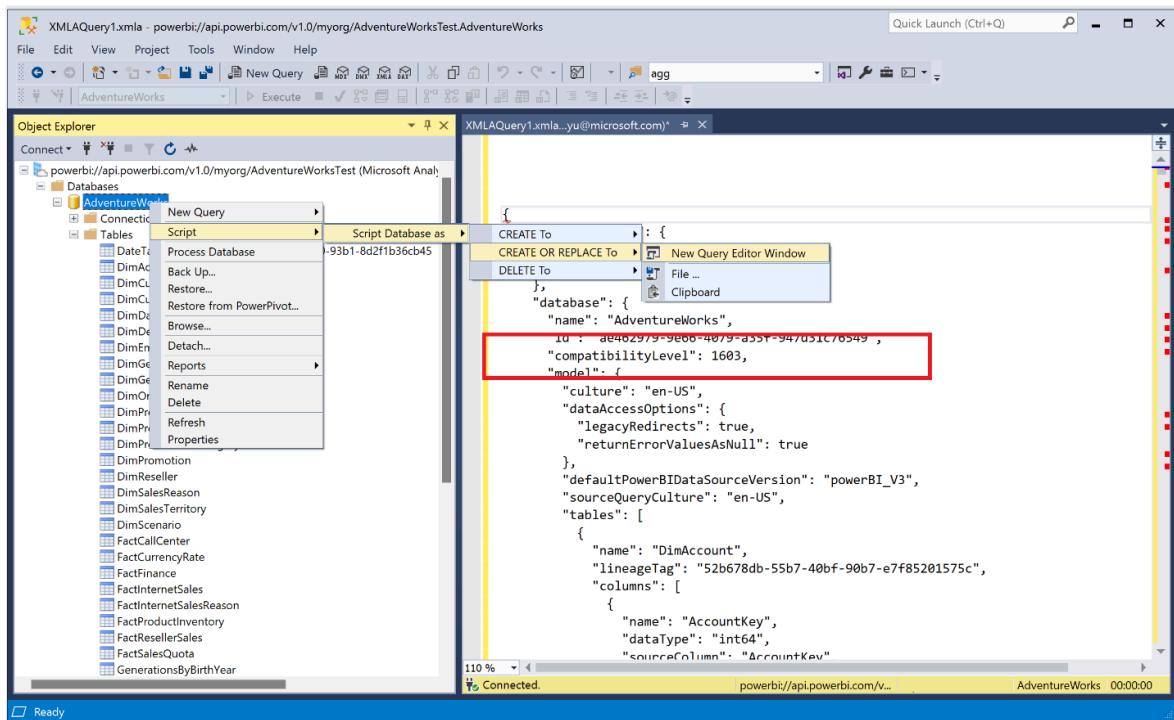

How to use hot and cold table partitions

First, configure the sales table with a **hot** import mode partition for the most recent data and keep the older data in a **cold** *DirectQuery* partition, as the following diagram illustrates for the FactInternetSales table of an AdventureWorks sample data model. Any rows with an *OrderDateKey* greater than or equal to 20200101 are imported into the data model via the hot import-mode partition. Rows with an *OrderDateKey* less than 20200101 are covered through the cold *DirectQuery* partition. Now, Power BI can deliver the primary use cases quickly with import mode, and you don't need to import vast volumes of historical data that you only analyze occasionally because the *DirectQuery* partition has this covered.

If you have an [AdventureWorks sample data warehouse](#) and want to follow along, here are the general steps:

- Create the dataset.** Use Power BI Desktop to create an AdventureWorks dataset and report. Include all the tables in pure *DirectQuery* mode. Then, convert all the tables except the `FactInternetSales` table to *Dual* mode. Leave the `FactInternetSales` table in *DirectQuery* mode.
- Upload the dataset.** Use a workspace hosted on Power BI Premium with the XMLA endpoint enabled for write operations.
- Update the compatibility level.** Open the workspace with your AdventureWorks dataset in SQL Server Management Studio (SSMS). Right click the **AdventureWorks** dataset > Script > **Script Database as Create or Replace to**, and select **New query editor window**. Set the compatibilityLevel property to 1603 (or higher). Select **Execute** or press F5. Verify that the operation finishes successfully.

4. Configure the *FactInternetSales* table partitions. Right click the AdventureWorks dataset > Script > Script Database as Create or Replace to, and select New query editor window. Replace the entire partitions section with the following section. Make sure you update the Sql.Database lines to point to the *AdventureWorksDW* database in your environment. Select Execute or press F5. Verify that the operation finishes successfully.

JSON

```

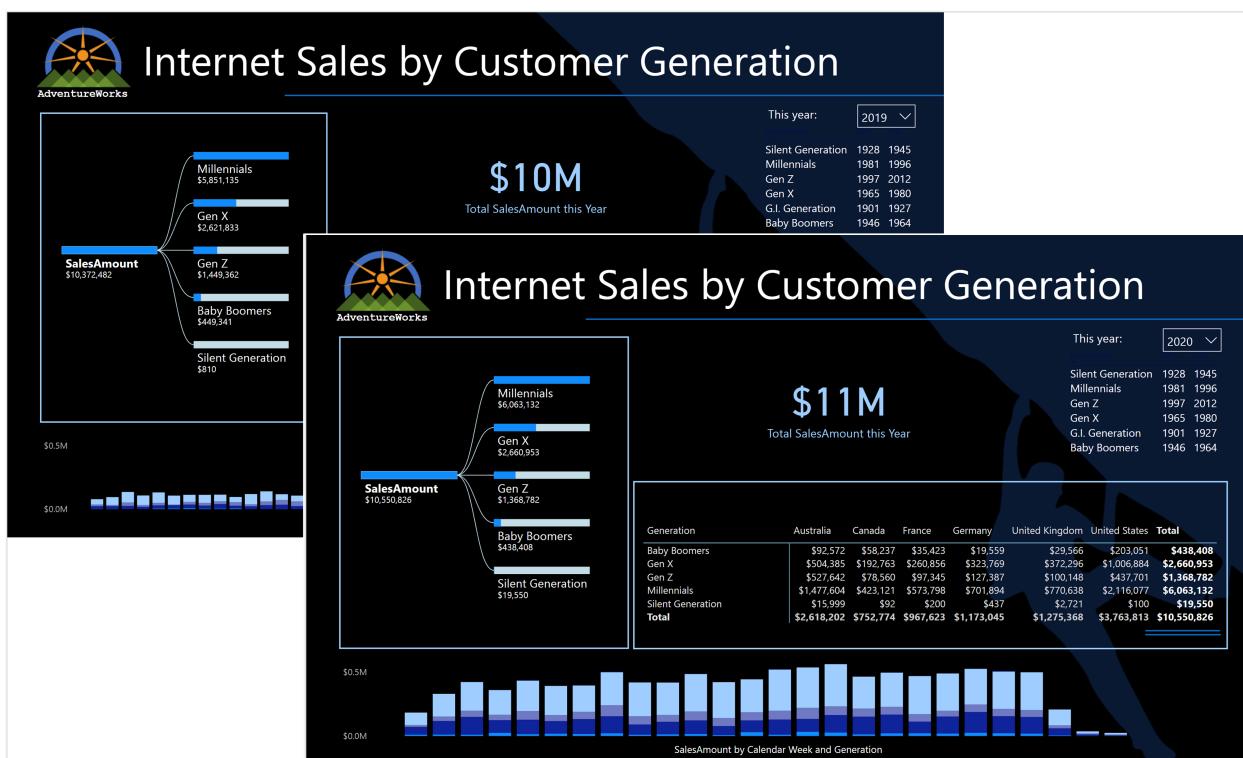

"partitions": [
    {
        "name": "FactInternetSales-DQ-Partition",
        "mode": "directQuery",
        "dataView": "full",
        "source": {
            "type": "m",
            "expression": [
                "let",
                "    Source = Sql.Database(\"demo.database.windows.net\",
\"AdventureworksDW\"),",
                "    dbo_FactInternetSales =
Source{[Schema=\"dbo\",Item=\"FactInternetSales\"]}[Data],",
                "    #\"Filtered Rows\" =
Table.SelectRows(dbo_FactInternetSales, each [OrderDateKey] <
20200101)",
                "    in",
                "    #\"Filtered Rows\""
            ]
        }
    },
    {
        "name": "FactInternetSales-Import-Partition",
    }
]
  
```

```

"mode": "import",
"source": {
    "type": "m",
    "expression": [
        "let",
        "    Source = Sql.Database(\"demo.database.windows.net\",
\"AdventureWorksDW\"),",
        "    dbo_FactInternetSales =
Source{[Schema=\"dbo\",Item=\"FactInternetSales\"]}[Data],",
        "    #\"Filtered Rows\" =
Table.SelectRows(dbo_FactInternetSales, each [OrderDateKey] >=
20200101)",
        "    in",
        "    #\"Filtered Rows\""
    ]
}
],

```

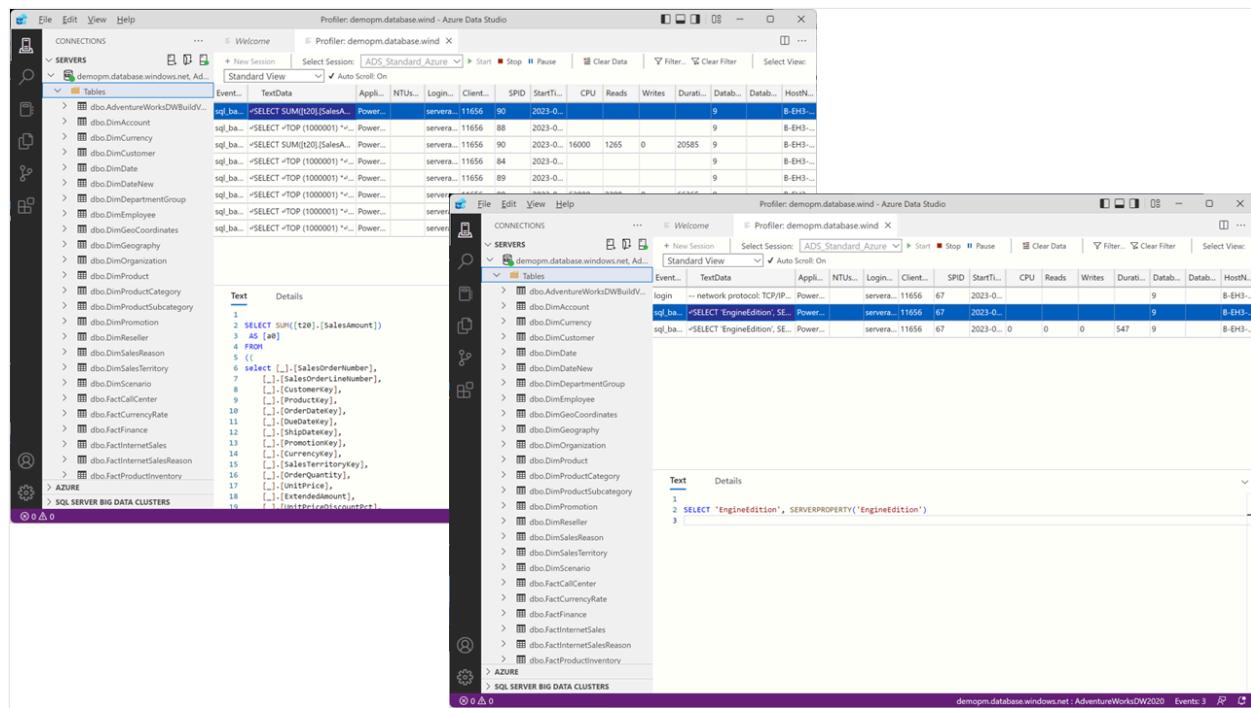

5. **Process the data model.** In the Power BI portal, open the workspace with your *AdventureWorks* dataset and perform an on-demand refresh of the dataset to load the import partition with data.
6. **Verify that the reports show recent and historical data.** Open your *AdventureWorks* and verify that the report is able to show results for sales transactions before and after Jan 1, 2020, as in the following screenshot.

Define the data coverage of the *DirectQuery* partition

The solution works seamlessly over recent and historical data. However, by default Power BI queries all table partitions, because it doesn't know what data each partition covers. Therefore, Power BI still queries the DirectQuery partition even for those years that the DirectQuery partition doesn't cover. The sales data is readily available in the import partition and the DirectQuery partition doesn't contribute any rows, but this superfluous source querying can still cause noticeable load on the data source and contribute delays to DAX query processing. To avoid this superfluous source querying, use the `DataCoverageDefinition`.

As the following screenshot shows, the Power BI report still sends several unnecessary SQL queries for 2020 to the data source as each visual's DAX query causes Power BI to query the *DirectQuery* partition.

By setting the `DataCoverageDefinition` property on the *DirectQuery* partition as in the following TMSL snippet, these SQL queries are avoided. Keep in mind, however, that you must refresh the dataset after you apply or change a data coverage definition. A process `recalc` is enough to evaluate the data coverage definition. If you forget this step, queries that touch the partition fail with an error message stating "DataCoverageDefinition of the DQ partition in table '[Table Name]' is not yet calculated after a recent change. It needs to be reprocessed".

JSON

```

{
    "name": "FactInternetSales-DQ-Partition",
    "mode": "directQuery",
    "dataView": "full",
    "source": {
        "type": "m",
        "expression": [
            "let",
            "    Source = Sql.Database(\"demopm.database.windows.net\",
\"AdventureWorksDW2020\"),",
            "    dbo_FactInternetSales =
Source{[Schema=\"dbo\",Item=\"FactInternetSales\"]}[Data],",
            "    #\"Filtered Rows\" =
Table.SelectRows(dbo_FactInternetSales, each [OrderDateKey] < 20200101)",
            "    in",
            "    #\"Filtered Rows\""
        ]
    },
    "dataCoverageDefinition": {
        "description": "DQ partition with all sales from 2017,
2018, and 2019.",
        "expression": "RELATED('DimDate'[CalendarYear]) IN
{2017,2018,2019}"
    }
}

```

As mentioned earlier, the `dataCoverageDefinition` property helps eliminate unnecessary data source load. It also improves the analysis performance for recent data because now Power BI can exclude the DirectQuery partition from DAX query processing where appropriate. You can define straightforward data coverage expressions for single values as well as ranges with simple AND, OR, and NOT operators. You can also use the RELATED function to define the data coverage based on a column from a dimension table that has a regular relationship to the fact table. If a data coverage expression uses columns from a dimension table, make sure the dimension table is in *dual* mode. You can also define the data coverage based on columns from the fact table itself. Refer to the following table for supported operations, categorized into three groups.

[\[\] Expand table](#)

Type	Comments	Examples
Single predicate (value based)	Equality, inequality, and IN operators Support both dimension and fact tables	RELATED('Date'[Year]) = 2020 NOT RELATED('Date'[Year]) = 2020 RELATED('Date'[Year]) IN {2020, 2021, 2022} InternetSales'[SalesAmt] = CURRENCY(100.0) NOT InternetSales'[SalesAmt] = CURRENCY(100.0)

Type	Comments	Examples
		InternetSales'[SalesAmt] IN {CURRENCY(100.0), CURRENCY(200.0)}
Single predicate (range based)	<p>Can be comparison operators like $>$, $<$, \geq, \leq</p> <p>Require the dimension table to be in Dual mode</p>	RELATED('Date'[Year]) $>$ 2020 RELATED('Date'[Year]) \leq 2020
Multiple predicates	<p>Equality, inequality, and comparison</p> <p>Does not support IN operator</p> <p>Limited to a single dimension table in dual mode</p>	RELATED('Date'[Year]) $>$ 2010 $\&\&$ RELATED('Date'[Year]) $>$ 2020 RELATED('Date'[Year]) $=$ 2020 $\&\&$ RELATED('Date'[Calendar Quarter]) $=$ 1 RELATED('Date'[Year]) $>$ 2020 $\&\&$ NOT RELATED('Date'[Calendar Quarter]) $=$ 1 RELATED('Date'[Year]) $>$ 2020 $\&\&$ RELATED('Date'[Calendar Quarter]) $<$ 3 RELATED('Date'[Year]) $>$ 2020 $\&\&$ (RELATED('Date'[Calendar Quarter]) $=$ 1 RELATED('Date'[Calendar Quarter]) $=$ 2)

The `DataCoverageDefinition` property on *DirectQuery* partitions enables you to optimize even the largest Power BI data models based on hot partitions in import mode and cold partitions in *DirectQuery* mode by avoiding unnecessary querying of the data source. This source query reduction helps to boost report performance when analyzing hot data. It also helps to decrease the load on the data source, and in this way helps to maximize the scale of your data source. Yet, keep in mind that optimizing a data model by using the `dataCoverageDefinition` property is still an advanced scenario. Make sure you verify the results carefully.

Considerations and limitations

- Currently, the `DataCoverageDefinition` property on *DirectQuery* partitions requires static values, such as `RELATED('Date'[Year]) = 2020` or `RELATED('Date'[Year]) IN {2020, 2021, 2022}`. Dynamic assignments are not supported, such as `RELATED('Date'[DateKey]) = TODAY()`.
- Incremental refresh with real-time data does not leverage the `DataCoverageDefinition` property. If you apply a data coverage definition to a *DirectQuery* (real-time) partition, Incremental Refresh drops the data coverage definition when recreating the partition.

Lineage tags for Power BI semantic models

Article • 01/06/2025

You can use [lineage tags](#) in semantic model objects to enable stable identification of such objects across different semantic models. Using lineage tags enables Power BI features such as [composite models](#) to maintain their binding to referenced tables or columns (by use of [SourceLineageTag](#)), even if the source semantic model object is renamed.

Lineage tags must be unique within their scope; for instance, two tables in the same semantic model can't have the same lineage tag. Power BI Desktop typically assigns a GUID for each semantic model object requiring lineage, but such assignment is not mandatory and lineage tags can be changed to any other string format.

ⓘ Important

If semantic model objects don't have a lineage tag, Power BI defaults to using the object name, which can lead to the loss of customizations if the object is renamed.

Tracking user customizations to semantic models

Semantic models can include objects and properties derived from other models or data sources. For example, when creating a [composite model on Power BI semantic models](#), the table and column names, data types, format strings, and other properties originate from the source model.

When customizing properties or removing objects in the model that have been synced from the data source, Power BI expects the [changedProperties property](#) and [*PBI_RemovedChildren*](#) annotation to be set to indicate a user customization so that the customizations are maintained during the next schema synchronization with the data source.

The following objects/properties synchronize with the data source and require you to declare both any modified properties and object removals:

[+] [Expand table](#)

Scenario	Objects	Property customization	Removal customization
Import / DirectQuery	Tables, Columns, Relationships	Name, DataType	Relationships ¹
Composite	Tables, Columns, Relationships, Measures, Hierarchies, Levels	Name, DataType, IsHidden, FormatString, Description, SummarizeBy, DataCategory, SortByColumn, GroupByColumns, DisplayFolder, IsNullable	All tables in the remote model not included in the local model
DirectLake	Tables, Columns	Name, DataType	All tables in the Lakehouse not included in the model

[1] Power BI automatically creates relationships based on primary and foreign key information from the data source. If users remove those relationships, Power BI keeps track of the changes to prevent re-adding them during future schema synchronization.

The *ChangedProperties* collection

The *ChangedProperties* collection enables you to specify which object property values have been modified, indicating that those values may no longer be synchronized with the source.

For example, when creating a composite model on Power BI semantic models, the column names originate from the source model. If you rename a column in your local model, you need to specify the *Name* property as a changed property.

In the following example, the *ProductID* column from the source model was renamed to *ProductKey*:

```
TMDL

table Products

    column ProductKey
        dataType: int64
        lineageTag: 9636345e-0328-43fb-acd3-e7894734d08a
        sourceLineageTag: 6890686b-4899-4916-9ec2-2e8ff5a05eb7
        sourceColumn: ProductID

        changedProperty = Name
```

The PBI_RemovedChildren annotation

The *PBI_RemovedChildren* annotation is a model annotation declared on the parent object of the removed item that declares the user's intent to exclude an object from the local object. For example, when constructing a composite model you [can choose which tables to load](#), and all the non-selected tables are included in the *PBI_RemovedChildren* annotation stored in the *NamedExpression* of the data source. In Import and DirectQuery models, the annotation is stored within the model to keep track of relationship removals.

Not declaring this annotation causes semantic model objects to be retrieved during schema synchronization with the source.

In the following example a table is removed from the composite model. The lineage tag of the source model table is used instead of its name to ensure a stable identification:

```
TMDL

expression 'DirectQuery to AS - AdventureWorks' =
    let
        Source = AnalysisServices.Database("[XMLA Endpoint]"),
        Cubes = Table.Combine(Source[Data]),
        Cube = Cubes{[Id="Model", Kind="Cube"]}[Data]
    in
        Cube

    annotation PBI_RemovedChildren = [{"remoteItemId":
        {"analysisServicesObject": {"sourceName": null, "sourceLineageTag": "8e47b52e-1c1a-4029-b6cc-25200d213fcf"}}, "objectType": "Table"}]
```

Considerations and limitations

- For Import/DirectQuery models, the *changedProperty* is required only when the change cannot be folded into the M query of the table, such as in DirectQuery tables utilizing a native query.
- For DirectLake models, the *sourceLineageTag* must be the name of the table/column in the Lakehouse/data warehouse.

Next step

The following articles contain useful additional information:

- [Model write support with the XMLA endpoint](#)
- [XMLA modifications and composite models](#)

Tabular Model Scripting Language (TMSL) Reference

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Tabular Model Scripting Language (TMSL) is the command and object model definition syntax for tabular data models at compatibility level 1200 or higher. TMSL communicates with Analysis Services through the XMLA protocol, where the `XMLA.Execute` method accepts both JSON-based **statement** scripts in TMSL as well as the traditional XML-based scripts in Analysis Services Scripting Language (ASSL for XMLA).

Key elements of TMSL:

- Tabular metadata based on tabular model semantics.

A tabular model is composed of tables, columns, and relationships. Equivalent object definitions in TMSL are now, not surprisingly, tables, columns, relationships, and so forth. A new metadata engine supports these definitions.

- Object definitions are structured as JSON instead of XML.

With the exception of how the payload is formatted (in either JSON or XML), both TMSL and ASSL are functionally equivalent in how they provide commands and metadata to XMLA methods used for server communication and data transfer.

How to use TMSL

The easiest way to explore TMSL scripting is using the CREATE, ALTER, DELETE, or Process commands in SQL Server Management Studio (SSMS) on a model you already know.

1. Find the command you want to use: [TMSL Reference - Commands](#)
2. Check the object definition reference for objects used in the command: [TMSL Reference - Objects](#)
3. Choose a method for executing the TMSL script:
 - XMLA window in SSMS

- [Invoke-ASCmd](#) PowerShell cmdlet
- [Analysis Services Execute DDL Task](#) in SSIS.

Model definition schema

The following screenshot shows an abbreviated version of the schema, collapsed to show the major objects.

```
{

    }
  },
  "additionalProperties": false
}
```

Scripting languages in Analysis Services

Analysis Services supports ASSL and TMSL scripting languages. Only tabular models created at the 1200 compatibility level or higher are described in TMS in JSON format.

Analysis Services Scripting Language (ASSL for XMLA) was the first scripting language, and is still the only scripting language for Multidimensional models and Tabular models

at lower compatibility levels (1100 or 1103). In ASSL, tabular models at 110x are described in multidimensional terms, such as **cube** (for a model) and **measuregroup** (for a table).

Note

In [SQL Server Data Tools (SSDT)], you can upgrade an earlier version tabular model to use TMSL by switching up its **CompatibilityLevel** to 1200 or higher. Remember that upgrade is irreversible. Prior to upgrading, back up your model in case you need the original version later.

The following table is the scripting language matrix for Analysis Services data models across different platforms/versions at specific compatibility levels.

TMSL Reference - Commands overview

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

You can execute commands on an XMLA endpoint, formulating object definitions in JSON using the Tabular Model Scripting Language (TMSL), against tabular model databases. See [TMSL Reference - Objects overview](#) for a list of objects used with the following commands.

Object operations

Expand table

Command	Description
Alter command (TMSL)	Make inline modifications to an object without having to specify the full definition.
Create command (TMSL)	Creates a new object, including its descendants.
CreateOrReplace command (TMSL)	Create or replace parts of an object definition. The full definition must be provided.
Delete command (TMSL)	Delete an object, including its descendants.

Data refresh operations

Expand table

Command	Description
MergePartitions command (TMSL)	Merge a target partition into a source, and delete the target.
Refresh command (TMSL)	Process a database, table, or partition.

Scripting

Expand table

Command	Description
Sequence command (TMSL)	Batch operations sequentially or in parallel

Database management operations

 [Expand table](#)

Command	Description
Attach command (TMSL)	Adds a file to the server.
Detach command (TMSL)	Removes a file from the servers.
Backup command (TMSL)	Creates a backup file of a database.
Restore command (TMSL)	Restores database to the server.
Synchronize command (TMSL)	Synchronizes a tabular database with another existing database.

Alter command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Alters an existing object, but not its children. If the object does not exist, the command raises an error.

Use **Alter** command for targeted updates, like setting a property on a table without having to specify all of the columns as well. This command is similar to **CreateOrReplace**, but without the requirement of having to provide a full object definition.

For objects having read-write properties, if you specify one read-write property, you will need to specify all of them, using new or existing values. You can use AMO PowerShell to get a property list.

Request

Alter does not have any attributes. Inputs include the object to be altered, followed by the modified object definition.

The following example illustrates the syntax for changing a property on a partition object. The object path establishes which partition object is to be altered via name-value pairs of parent objects. The second input is a partition object that specifies the new property value.

JSON

```
{  
  "alter": {  
    "object": {  
      "database": "\<database-name>",  
      "table": "\<table-name>",  
      "partition": "\<partition-name>"  
    },  
    "partition": {  
      "name": "\<new-partition-name>",  
      . . . << other properties  
    }  
  }  
}
```

The structure of the request varies based on the object. **Alter** can be used with any of the following objects:

[Database object \(TMSL\)](#) Rename a database.

JSON

```
"alter": {  
    "object": {  
        "database": "\<database-name>"  
    },  
    "database": {  
        "name": "\<new-database-name>",  
    }  
}
```

[DataSources object \(TMSL\)](#) Rename a connection, which is a child object of database.

JSON

```
{  
    "alter":{  
        "object":{  
            "database":"AdventureWorksTabular1200",  
            "dataSource":"SqlServer localhost AdventureworksDW2016"  
        },  
        "dataSource":{  
            "name":"A new connection name"  
        }  
    }  
}
```

[Tables object \(TMSL\)](#) See [Example 1](#) below.

[Partitions object \(TMSL\)](#) See [Example 2](#) below.

[Roles object \(TMSL\)](#) Change a property on a role object.

JSON

```
{  
    "alter":{  
        "object":{  
            "database":"AdventureWorksTabular1200",  
            "role":"DataReader"  
        },  
        "role":{  
            "name":"New Name"  
        }  
    }  
}
```

```
}
```

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Examples

The following examples demonstrate script that you can run in an XMLA window in Management Studio or use as input in Invoke-ASCmd cmdlet in AMO PowerShell.

Example 1 - This script changes the name property on a table.

JSON

```
{
  "alter": {
    "object": {
      "database": "AdventureWorksDW2016",
      "table": "DimDate"
    },
    "table": {
      "name": "DimDate2"
    }
  }
}
```

Assuming a local named instance (instance name is "tabular") and a JSON file with the alter script, this command changes a table name from DimDate to DimDate2:

```
invoke-ascmd -inputfile '\\my-computer\my-shared-folder\altertablename.json' -
server 'localhost\Tabular'
```

Example 2 -- This script renames a partition, for example at year end when the current year becomes the previous year. Be sure to specify all of the properties. If you leave **source** unspecified, it could break all of your existing partition definitions.

Unless you are creating, replacing, or altering the data source object itself, any data source referenced in your script (such as in the partition script below) must be an existing **DataSource** object in your model. If you need to change the data source, do so as a separate step.

JSON

```
{  
    "alter": {  
        "object": {  
            "database": "InternetSales",  
            "table": "DimDate",  
            "partition": "CurrentYear"  
        },  
        "partition": {  
            "name": "Year2009",  
            "source": {  
                "query": "SELECT [dbo].[DimDate].* FROM [dbo].[DimDate] WHERE  
[dbo].[DimDate].CalendarYear = 2009",  
                "dataSource": "SqlServer localhost AdventureworksDW2016"  
            }  
        }  
    }  
}
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You cannot generate a ready-made script for this command from SSMS. Instead, you can start with an example or write your own.

Attach command (TMSL)

Article • 12/09/2022

Applies to: ✓ SQL Server 2016 and later Analysis Services ✓ Azure Analysis Services
✓ Fabric/Power BI Premium

Attaches a tabular database file to a server.

Request

JSON

```
{  
  "attach":{  
    "folder":"C:\\Program Files\\Microsoft SQL  
Server\\MSAS13.Tabular\\OLAP\\Data\\",  
    "readWriteMode":"readOnly",  
    "password":"secret"  
  }  
}
```

The properties accepted by the JSON attach command are as follows.

[] Expand table

Property	Default	Description
database	[Required]	The name of the database object to be attached.
folder	[Required]	The folder that contains the attached database.
password	Empty	The password to use to encrypt secrets in the attached database.
readWriteMode	readWrite	An enumeration value that indicates the access modes allowed to the database. The enumeration values are as follows: readWrite – Read-write access is allowed. readOnly – Read-only access is allowed. readOnlyExclusive – Read-only exclusive access is allowed.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS by clicking the Script button on the Attach Database dialog box.

Backup command (TMSL)

Article • 12/09/2022

Applies to: ✓ SQL Server 2016 and later Analysis Services ✓ Azure Analysis Services
✓ Fabric/Power BI Premium

Backs up a tabular database to an .abf backup file.

Request

JSON

```
{  
    "backup": {  
        "description": "Parameters of Backup command of Analysis  
Services JSON API",  
        "properties": {  
            "database": {  
                "type": "string"  
            },  
            "file": {  
                "type": "string"  
            },  
            "password": {  
                "type": "string"  
            },  
            "allowOverwrite": {  
                "type": "boolean"  
            },  
            "applyCompression": {  
                "type": "boolean"  
            }  
        },  
        ...  
    },  
    ...  
}
```

Backup has several properties.

[] Expand table

Property	Default	Description
database	[Required]	The name of the database object to be backed up.
file	[Required]	The backup file name/path.
password	Empty	The password to use for encrypting the backup file.

Property	Default	Description
allowOverwrite	False	A Boolean that, when true, indicates that a backup file that already exists will be overwritten; otherwise false.
applyCompression	True	A Boolean that, when true, indicates that backup files are compressed; otherwise false.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Examples

Example 1 - Backup a file to the default backup folder.

JSON

```
{
  "backup": {
    "database": "AS_AdventureWorksDW2014",
    "file": "AS_AdventureWorksDW2014.abf",
    "password": "secret"
  }
}
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS by clicking the Script button on the Backup Database dialog box.

Create command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Creates the specified object and all of the descendant objects that are specified. If the object already exists, the command raises an error.

Request

The structure of the request varies based on the object. An object that is a parent must include all of its children, although the full object definitions of siblings and parent(s) are not required.

[Database object \(TMSL\)](#) Add a database to a server.

JSON

```
{  
  "create": {  
    "database": {  
      "name": "AdventureworksDW2016",  
      "description": "<description>"  
    }  
  }  
}
```

[DataSources object \(TMSL\)](#)

JSON

```
{  
  "create": {  
    "parentObject": {  
      "database": "AdventureworksDW2016"  
    },  
    "dataSource": {  
      "name": "SqlServer localhost AdventureworksDW2016",  
      "connectionString": "Provider=SQLNCLI11;Data Source=localhost;Initial  
Catalog=AdventureworksDW2016;Integrated Security=SSPI;Persist Security  
Info=false",  
      "impersonationMode": "impersonateAccount",  
      "account": "<account name>",  
      "annotations": [  
        {  
          "id": 1,  
          "text": "This is a comment."  
        }  
      ]  
    }  
  }  
}
```

```

        "name": "ConnectionEditUISource",
        "value": "SqlServer"
    }
]
}
}
}

```

Partitions object (TMSL) Add a partition to a parent table object.

JSON

```
{
  "create": {
    "parentObject": {
      "database": "AdventureWorksTabular1200",
      "table": "Date"
    },
    "partition": {
      "name": "Date 2",
      "source": {
        "query": "SELECT [dbo].[DimDate].* FROM [dbo].[DimDate]",
        "dataSource": "SqlServer localhost AdventureworksDW2016"
      }
    }
  }
}
```

Roles object (TMSL) Minimally add a role to a database, but without membership or filters.

JSON

```
{
  "create": {
    "parentObject": {
      "database": "AdventureWorksDW2016"
    },
    "role": {
      "name": "DataReader",
      "modelPermission": "read"
    }
  }
}
```

Except for the **Database** object, the object being created is child of a specified **parentObject**. The parent of the **Database** object is always the **Server** object.

Server is assumed from the context. For example, if you run the script from Management Studio or AMO PowerShell, the server connection would be specified in the session or as a parameter.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLEA exception is returned.

Examples

Example 1 - Add a role that specifies membership and a filter.

JSON

```
{  
    "create":{  
        "parentObject":{  
            "database":"AdventureWorksTabular1200"  
        },  
        "role":{  
            "name":"DataReader",  
            "modelPermission":"read",  
            "members":[  
                {  
                    "memberName": "account-01",  
                    "memberId":"S-1-5-21-1111111111-2222222222-33333333-444444"  
                },  
                {  
                    "memberName": "account-02",  
                    "memberId":"S-2-5-21-1111111111-2222222222-33333333-444444"  
                }  
            ],  
            "tablePermissions": [  
                {  
                    "name":"Date",  
                    "filterExpression":"CalendarYear('2011')"  
                }  
            ]  
        }  
    }  
}
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLE) call over an XMLE endpoint, exposed in the following ways:

- As an XMLE window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS. For example, you can right-click an existing database > **Script** > **Script Database as** > **CREATE To**.

CreateOrReplace command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Creates or replaces the specified object and all the descendant objects that are specified. Non-existent objects are created. Existing objects are replaced with the new definition.

Whenever you specify a read-write property, make sure to include them all. Omission of a read-write object is considered a deletion.

Request

The structure of the request varies based on the object. An object that is a parent must include all of its children, although the full object definitions of siblings and parent(s) are not required.

[Database object \(TMSL\)](#)

Replaces an existing database with a renamed, minimal database definition that specifies its name, modified model properties, and a connection. Because the object definition does not include tables, partitions, or relationships, all of those objects are deleted.

```
JSON

{
  "createOrReplace": {
    "object": {
      "database": "AdventureWorksTabular1200"
    },
    "database": {
      "name": "TestCreateOrReplaceDB",
      "id": "newID",
      "compatibilityLevel": 1200,
      "model": {
        "defaultMode": "import",
        "culture": "en-US",
        "dataSources": [
          {
            "name": "SqlServer localhost AdventureworksDW2016",
            "connectionString": "Provider=SQLOLEDB;Data
Source=localhost;Initial Catalog=AdventureworksDW2016;Integrated
Security=SSPI;Persist Security Info=false",
            "type": "OLE DB"
          }
        ]
      }
    }
  }
}
```

```
        "impersonationMode": "impersonateAccount",
        "account": "",
        "annotations": [
            {
                "name": "ConnectionEditUISource",
                "value": "SqlServer"
            }
        ]
    }
}
}
```

[DataSources object \(TMSL\)](#) Replaces a connection name.

JSON

```
{  
  "createOrReplace": {  
    "object": {  
      "database": "TestCreateOrReplaceDB",  
      "dataSource": "SqlServer localhost AdventureworksDW2016"  
    },  
    "dataSource": {  
      "name": "New connection name",  
      "connectionString": "Provider=SQLNCLI11;Data Source=localhost;Initial Catalog=AdventureworksDW2016;Integrated Security=SSPI;Persist Security Info=false",  
      "impersonationMode": "impersonateAccount",  
      "account": " ",  
      "annotations": [  
        {  
          "name": "ConnectionEditUISource",  
          "value": "SqlServer"  
        }  
      ]  
    }  
  }  
}
```

[Tables object \(TMSL\)](#) Overwrites any existing tables, leaving just the one specified.

JSON

```
{  
  "createOrReplace": {  
    "object": {  
      "database": "AdventureWorksTabular1200"  
    },  
    "database": {

        },
        {
          "name": "_TM_ExtProp_DbTableName",
          "value": "DimDate"
        },
        {
          "name": "_TM_ExtProp_DbSchemaName",
          "value": "dbo"
        }
      ]
    }
  ]
}
```

Partitions object (TMSL)

Replace a partition name. Partition objects have three read-write properties: name, source, description. Whenever you specify a read-write property, make sure to include them all. Omission of a read-write object is considered a deletion.

Because the object definition is the partition, only the named partition and its definition is impacted. Other tables, relationships, and partitions are unaffected.

Unless you are creating, replacing, or altering the data source object itself, any data source referenced in your script (such as in the partition script below) must be an existing **DataSource** object in your model. If you need to change the data source, add it to

JSON

```
{
  "createOrReplace": {
    "object": {
      "database": "AdventureWorksTabular1200",
      "table": "FactSalesQuota",
      "partition": "FactSalesQuota - 2011"
    },
    "partition": {
      "name": "Sales Quota for 2011",
      "mode": "import",
      "dataView": "full",
      "source": {
        "table": "FactSalesQuota"
      }
    }
  }
}
```

```

    "query": [
        "SELECT [dbo].[FactSalesQuota].* FROM [dbo].[FactSalesQuota]",
        "JOIN DimDate as DD",
        "on DD.DateKey = FactSalesQuota.DateKey",
        "WHERE DD.CalendarYear='2011'"
    ],
    "dataSource": "SqlServer localhost AdventureworksDW2016"
}
}
}
}

```

[Roles object \(TMSL\)](#) Replaces a role definition with one that includes members.

JSON

```
{
  "createOrReplace": {
    "object": {
      "database": "AdventureWorksTabular1200",
      "role": "DataReader"
    },
    "role": {
      "name": "DataReader",
      "modelPermission": "read",
      "members": [
        {
          "memberName": "ADVENTUREWORKS\\InternalSalesGrp"
        }
      ]
    }
  }
}
```

Response

Returns an empty result when the command succeeds. Otherwise, an XMLEA exception is returned.

Examples

Example 1 - Creates a new database, overwriting an existing database of the same name.

JSON

```
{
  "createOrReplace": {
    "object": {
      "database": "AdventureWorksTabular1200"
    },
    "database": {
      "name": "AdventureWorksTabular1200",
      "id": "AdventureWorksTabular1200",
      "compatibilityLevel": 1200,
      "model": {
        "defaultMode": "directQuery",
        "culture": "en-US",
        "dataSources": [

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS. For example, you can right-click an existing database > **Script** > **Script Database as** > **CREATE** or **REPLACE To**.

Delete command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Deletes a database or an object in the current database. It deletes the specified object and all child objects and collections. If the object does not exist, the command raises an error.

Request

The object being deleted is specified by using the object path. For example, deleting a partition requires that you specify the table and database objects that precede it.

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016",  
      "table": "Reseller Sales",  
      "partition": "may2011"  
    }  
  }  
}
```

You can delete the following objects:

[Database object \(TMSL\)](#)

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016"  
    }  
  }  
}
```

[DataSources object \(TMSL\)](#)

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016",  
      "dataSource": "SqlServer localhost AdventureworksDW2016"  
    }  
  }  
}
```

Tables object (TMSL)

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016",  
      "table": "Reseller Sales",  
    }  
  }  
}
```

Partitions object (TMSL)

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016",  
      "table": "Reseller Sales",  
      "partition": "may2011"  
    }  
  }  
}
```

Roles object (TMSL)

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureworksDW2016",  
      "role": "Data Reader"  
    }  
  }  
}
```

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Examples

Example 1 - Delete a database.

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureWorksDW2016"  
    }  
  }  
}
```

Example 2 - Delete a connection.

JSON

```
{  
  "delete": {  
    "object": {  
      "database": "AdventureWorksDW2016",  
      "dataSource": "SqlServer localhost AdventureworksDW2016"  
    }  
  }  
}
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS. For example, you can right-click an existing database > **Script** > **Script Database as** > **DELETE To**.

Detach command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Detaches a tabular database from a server.

Request

JSON

```
{  
  "detach": {  
    "database": "AdventureWorksDW2014",  
    "password": "secret"  
  }  
}
```

The properties accepted by the JSON detach command are as follows.

Expand table

Property	Default	Description
database	[Required]	The name of the database object to be detached.
password	Empty	The password to use to encrypt secrets in the detached database.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet

- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS by clicking the Script button on the Detach dialog box.

MergePartitions command (TMSL)

Article • 12/09/2022

Applies to: ✓ SQL Server 2016 and later Analysis Services ✓ Azure Analysis Services
✓ Fabric/Power BI Premium

Merges the data of one or more source partitions into a target partition, and then deletes the source partition. The SQL Query of the target partition will not be updated as part of the merge. To ensure that subsequent processing of the partition retrieves all of the data, you should revise the query so that it selects all of the data in the merged partition.

Request

You must specify the database, table, and source and target partitions. You can only merge partitions from the same table.

JSON

```
{
  "mergePartitions": {
    "target": {
      "database": "salesdatabase",
      "table": "sales",
      "partition": "may2015"
    },
    "sources": [
      {
        "database": "salesdatabase",
        "table": "Sales",
        "partition": "partition1"
      },
      {
        "database": "salesdatabase",
        "table": "Sales",
        "partition": "partition2"
      }
    ]
  }
}
```

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS. For example, you can click the **Script** in Partition Management dialog box.

Refresh command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Processes objects in the current database.

Refresh always runs in parallel unless you throttle it with [Sequence command \(TMSL\)](#).

You can override some properties of some objects during a data refresh operation:

- Change the **QueryDefinition** property of a **Partition** object to import data using an on-the-fly filter expression.
- Provide data source credentials as part of a **Refresh** command, in the **ConnectionString** property of a **DataSource** object. This approach could be considered more secure, as credentials are provided and used temporarily for the duration of the operation, rather than stored.
- Override default Power BI semantic model incremental refresh policy.

See the examples in this topic for an illustration of these property overrides.

Note

Unlike multidimensional processing, there is no special handling of processing errors for tabular processing.

Request

Refresh takes a type parameter and object definition.

JSON

```
{  
    "refresh": {  
        "description": "Parameters of Refresh command of Analysis  
Services JSON API",  
        "properties": {  
            "type": {  
                "enum": [  
                    "full",  
                    "clearValues",  
                    "calculate",  
                    "refresh",  
                    "refreshAll"  
                ]  
            }  
        }  
    }  
}
```

```

        "dataOnly",
        "automatic",
        "add",
        "defragment"
    ]
},
"objects": [

```

The **type** parameter sets a scope on the processing operation.

[Expand table](#)

Refresh type	Applies to	Description
full	Database, Table, Partition	For all partitions in the specified partition, table, or database, refresh data and recalculate all dependents. For a calculation partition, recalculate the partition and all its dependents.
clearValues	Database, Table, Partition	Clear values in this object and all its dependents.
calculate	Database, Table, Partition	Recalculate this object and all its dependents, but only if needed. This value does not force recalculation, except for volatile formulas.
dataOnly	Database, Table, Partition	Refresh data in this object and clear all dependents.
automatic	Database, Table, Partition	If the object needs to be refreshed and recalculated, refresh and recalculate the object and all its dependents. Applies if the partition is in a state other than Ready.
add	Partition	Append data to this partition and recalculate all dependents. This command is valid only for regular partitions and not for calculation partitions.
defragment	Database, Table	Defragment the data in the specified table. As data is added to or removed from a table, the dictionaries of each column can become polluted with values that no longer exist in the actual column values. The defragment option will clean up the values in the dictionaries that are no longer used.

You can refresh the following objects:

[Database object \(TMSL\)](#) Process a database.

JSON

```
{  
  "refresh": {  
    "type": "automatic",  
    "objects": [  
      {  
        "database": "AdventureWorksTabular1200"  
      }  
    ]  
  }  
}
```

[Tables object \(TMSL\)](#) Process a single table.

JSON

```
{  
  "refresh": {  
    "type": "automatic",  
    "objects": [  
      {  
        "database": "AdventureWorksTabular1200",  
        "table": "Date"  
      }  
    ]  
  }  
}
```

[Partitions object \(TMSL\)](#) Process a single partition within a table.

JSON

```
{  
  "refresh": {  
    "type": "automatic",  
    "objects": [  
      {  
        "database": "AdventureWorksTabular1200",  
        "table": "FactSalesQuota",  
        "partition": "FactSalesQuota"  
      },  
      {  
        "database": "AdventureWorksTabular1200",  
        "table": "FactSalesQuota",  
        "partition": "FactSalesQuota - 2011"  
      }  
    ]  
  }  
}
```

Optional parameters

For Power BI semantic models, the following parameters can be added to a TMSL refresh command to override the default incremental refresh behavior:

- **applyRefreshPolicy** – If a table has an incremental refresh policy defined, applyRefreshPolicy will determine if the policy is applied or not. If the policy is not applied, a process full operation will leave partition definitions unchanged and all partitions in the table will be fully refreshed. Default value is true.
- **effectiveDate** – If an incremental refresh policy is being applied, it needs to know the current date to determine rolling window ranges for the historical range and the incremental range. The effectiveDate parameter allows you to override the current date. This is useful for testing, demos, and business scenarios where data is incrementally refreshed up to a date in the past or the future (for example, budgets in the future). The default value is the current date.

```
JSON

{
  "refresh": {
    "type": "full",

    "applyRefreshPolicy": true,
    "effectiveDate": "12/31/2013",

    "objects": [
      {
        "database": "IR_AdventureWorks",
        "table": "FactInternetSales"
      }
    ]
  }
}
```

The following table shows the impact when **applyRefreshPolicy** is true (default) on each of the refresh types for a table that contains an incremental refresh policy:

 Expand table

Refresh type	Impact
full	The policy is applied as described in Incremental refresh in Power BI . Assuming historical partitions have already been created by a prior refresh operation, a summary is described here: <ul style="list-style-type: none">- New partitions are added to the incremental range if needed.

Refresh type	Impact
	<ul style="list-style-type: none"> - If no pollingExpression is defined for detection of data changes, all partitions in the incremental range are refreshed in full. - If a pollingExpression is defined, it is evaluated for each partition in the incremental range. Only those that return a different polling result compared to the previous refresh operation are refreshed in full. - Historical partitions are not refreshed regardless of whether they have been cleared of data. - Historical partitions that fall out of range are deleted. - Recalculation of affected partitions and dependents.
clearValues	applyRefreshPolicy does not affect behavior.
calculate	applyRefreshPolicy does not affect behavior.
dataOnly	Same as type=full, but without recalculation of affected partitions and dependents.
automatic	Same as type=full, but partitions in the incremental range are refreshed using type=automatic.
add	applyRefreshPolicy does not affect behavior.
defragment	applyRefreshPolicy does not affect behavior.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Examples

Override both the **ConnectionString** and **QueryDefinition** of a partition.

```
JSON
{
  "refresh": {
    "type": "dataOnly",
    "objects": [
      {
        "database": "AdventureWorksDW2017",
        "table": "DimCustomer"
      }
    ],
    "overrides": [
      {
        "dataSources": [ // Bindings for DataSources
          ...
        ]
      }
    ]
  }
}
```

```
{  
    "originalObject": {  
        "database": "AdventureWorksDW2017",  
        "dataSource": "SqlServer localhost"  
    },  
    "connectionString": "Provider=SQLNCLI11.1;Data Source=.;Persist  
Security Info=True;User ID=YourSQLLogin;Password=YourPassword;Initial  
Catalog=AdventureWorksDW2017"  
},  
],  
"partitions": [ // Bindings for Partitions  
{  
    "originalObject": {  
        "database": "AdventureWorksDW2017",  
        "table": "DimCustomer",  
        "partition": "DimCustomer"  
    },  
    "source": {  
        "query": "SELECT * FROM [dbo].[DimCustomer]"  
    }  
}  
]  
]  
}  
}
```

Scope particular overrides by setting the type parameter to a `dataOnly` refresh, metadata stays intact.

JSON

```
{  
  "refresh": {  
    "type": "dataOnly",  
    "objects": [  
      {  
        "database": "TMTTestDB",  
        "table": "Customer"  
      },  
      {  
        "database": "TMTTestDB",  
        "table": "Sales"  
      }  
    ],  
    "overrides": [  
      {  
        "scope": {  
          "database": "TMTTestDB",  
          "table": "Sales"  
        },  
        "dataSources": [  
          {  
            "name": "Customer",  
            "type": "dataOnly",  
            "table": "Customer",  
            "columns": [  
              {"name": "CustomerID", "type": "String", "isKey": true},  
              {"name": "CustomerName", "type": "String"},  
              {"name": "Address", "type": "String"},  
              {"name": "City", "type": "String"},  
              {"name": "State", "type": "String"},  
              {"name": "ZipCode", "type": "String"},  
              {"name": "Phone", "type": "String"},  
              {"name": "Email", "type": "String"},  
              {"name": "LastOrderDate", "type": "Date"},  
              {"name": "LastOrderTime", "type": "Time"},  
              {"name": "LastOrderQuantity", "type": "Integer"},  
              {"name": "LastOrderPrice", "type": "Decimal"},  
              {"name": "LastOrderStatus", "type": "String"},  
              {"name": "LastOrderComments", "type": "Text"},  
              {"name": "LastOrderOrderID", "type": "String"},  
              {"name": "LastOrderOrderDate", "type": "Date"},  
              {"name": "LastOrderOrderTime", "type": "Time"},  
              {"name": "LastOrderOrderQuantity", "type": "Integer"},  
              {"name": "LastOrderOrderPrice", "type": "Decimal"},  
              {"name": "LastOrderOrderStatus", "type": "String"},  
              {"name": "LastOrderOrderComments", "type": "Text"}  
            ]  
          }  
        ]  
      }  
    ]  
  }  
}
```

```
        "originalObject": {
            "dataSource": "SqlServer sqlcldb2 AS_foodmart_2000"
        },
        "connectionString": "Provider=SQLNCLI11;Data
Source=sqlcldb2;Initial Catalog=AS_foodmart_2000;Integrated
Security=SSPI;Persist Security Info=false"
    }
]
}
]
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS. For example, you can click the **Script** in a Processing dialog box.

Restore command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Restores a tabular database from a backup file.

Request

JSON

```
{
  "restore": {
    "description": "Parameters of Restore command of Analysis Services JSON API",
    "properties": {
      "database": {
        "type": "string"
      },
      "file": {
        "type": "string"
      },
      "password": {
        "type": "string"
      },
      "dbStorageLocation": {
        "type": "string"
      },
      "allowOverwrite": {
        "type": boolean
      },
      "readWriteMode": {
        "enum": [
          "readWrite",
          "readOnly",
          "readOnlyExclusive"
        ]
      }
    }
  }
}
```

Restore has several properties.

Expand table

Property	Default	Description
database	[Required]	The name of the database object to be restored.

Property	Default	Description
file	[Required]	The backup file name/path.
password	Empty	The password to use for decrypting the backup file.
allowOverwrite	False	A Boolean that, when true, indicates that a backup file that already exists will be overwritten; otherwise false.
readWriteMode	readWrite	An enumeration value that indicates the access modes allowed to the database. The enumeration values are as follows: readWrite – Read-write access is allowed. readOnly – Read-only access is allowed. readOnlyExclusive – Read-only exclusive access is allowed.
dbStorageLocation	Empty	Storage location for the restored database.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Example

Example 1 - Restore a database from a local folder.

JSON

```
{
  "restore": {
    "database": "AdventureWorksDW2014",
    "file": "c:\\awdbdwfile.abf",
    "security": "...",
    "allowOverwrite": "true",
    "password": "...",
    "locations": "d:\\SQL Server Analysis Services\\data\\",
    "storageLocation": "..."
  }
}
```

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLE) call over an XMLE endpoint, exposed in the following ways:

- As an XMLE window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS by clicking the Script button on the Restore dialog box.

Sequence command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Use the **Sequence** command to run a consecutive set of operations in batch mode on an instance of Analysis Services. The entire command and all of its component parts must complete in order for the transaction to succeed.

The following commands can be run sequentially, except for the **Refresh** command which runs in parallel to process multiple objects concurrently.

- [Create command \(TMSL\)](#)
- [CreateOrReplace command \(TMSL\)](#)
- [Alter command \(TMSL\)](#)
- [Delete command \(TMSL\)](#)
- [Refresh command \(TMSL\)](#)
- [Backup command \(TMSL\)](#)
- [Restore command \(TMSL\)](#)
- [Attach command \(TMSL\)](#)
- [Detach command \(TMSL\)](#)

Request

maxParallelism is an optional property that determines whether **Refresh** operations run sequentially or in parallel.

The default behavior is to use as much parallelism as possible. By embedding **Refresh** within **Sequence**, you can control the exact number of threads used during processing, including limiting the operation to just one thread.

Note

The integer assigned to **maxParallelism** determines the maximum number of threads used during processing. Valid values are any positive integer. Setting the

value to 1 equals not parallel (uses one thread).

Only Refresh runs in parallel. If you modify maxParallelism to use a fixed number of threads, be sure to review the properties on the [Refresh command \(TMSL\)](#) to understand the potential impact. It's possible to set properties in a way that undermines parallelism even when you've made multiple threads available. The following sequence of refresh types will give you the best degree of parallelism:

- First, specify Refresh for all objects using ClearValues
- Next, specify Refresh for all objects using DataOnly
- Last specify Refresh for all objects using Full, Calculate, Automatic or Add

Any variation on this will break parallelism.

JSON

```
{
  "sequence": [
    {
      "maxParallelism": 3,
      "operations": [
        {
          "mergepartitions": {
            "sources": [
              {
                "database": "salesdatabase",
                "table": "Sales",
                "partition": "partition1"
              },
              {
                "database": "salesdatabase",
                "table": "Sales",
                "partition": "partition2"
              }
            ]
          }
        },
        {
          "refresh": {
            "type": "calculate",
            "objects": [
              {
                "database": "salesdatabase"
              }
            ]
          }
        }
      ]
    }
  ]
}
```

```
}
```

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Usage (endpoints)

This command element is used in a statement of the Execute Method all over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You cannot generate a ready-made script for this command from SSMS. Instead, you can start with an example or write your own.

Synchronize command (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Synchronizes a tabular database with another existing database.

Request

The properties accepted by the JSON synchronize command are as follows.

```
JSON

{
    "synchronize": {
        "database": "AdventureWorksDW_Production",
        "source": "Provider=MSOLAP.7;Data Source=localhost;Integrated Security=SSPI;Initial Catalog=AdventureWorksDW_Dev",
        "synchronizeSecurity": "copyAll",
        "applyCompression": true
    }
}
```

The properties accepted by the JSON synchronize command are as follows.

Expand table

Property	Default	Description
database		The name of the database object to be synchronized.
source		The connection string to use to connect to the source server.
synchronizeSecurity	skipMembership	An enumeration value that specifies how to restore security definitions, including roles and permissions. Valid values includes skipMembership, copyAll, ignoreSecurity.
applyCompression	True	A Boolean that, when true, indicates that compression will be applied during the synchronization operation; otherwise false.

Response

Returns an empty result when the command succeeds. Otherwise, an XMLA exception is returned.

Usage (endpoints)

This command element is used in a statement of the Execute Method (XMLA) call over an XMLA endpoint, exposed in the following ways:

- As an XMLA window in SQL Server Management Studio (SSMS)
- As an input file to the **invoke-ascmd** PowerShell cmdlet
- As an input to an SSIS task or SQL Server Agent job

You can generate a ready-made script for this command from SSMS by clicking the Script button on the Synchronize Database dialog box.

TMSL Reference - Objects overview

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Applications that create, consume, or administer tabular databases or that connect to a server instance can use the Tabular Model Scripting Language (TMSL) for commands and object representations in JSON format.

This article documents the major objects of the TMSL schema used in scripts generated by SQL Server Management Studio, SQL Server Data Tools (SSDT), and AMO PowerShell.

Object definitions are in JSON and used in TMSL commands like Create, Alter, and Delete. See [TMSL Reference - Commands overview](#) for a list of commands.

Main objects

Commonly used objects in TMSL script:

Expand table

Object	Description
Database object (TMSL)	Defines a tabular database at compatibility level 1200 or higher, based on a model of the same level.
Model object (TMSL)	Defines a tabular model at compatibility level 1200 or higher.
DataSources object (TMSL)	Defines a connection to a data source used during import to load the model, or for pass through queries when the model is in DirectQuery mode.
Tables object (TMSL)	Specifies the tables of the model.
Partitions object (TMSL)	Defines storage of table rowsets, including calculated tables.
Relationships object (TMSL)	Defines the relationships between tables.
Roles object (TMSL)	Defines permissions, membership, and security filters that control access to data and operations.

Database object (TMSL)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines a tabular database at compatibility level 1200 or higher, based on a model of the same level. This topic documents the object definition of a database, providing the payload for requests that create, alter, delete, and perform database management tasks.

Note

In any script, only one database at the time can be referenced. For any object other than database itself, the Database property is optional if you specify the model.

There is one-to-one mapping between a Model and a Database that can be used to deduce the Database name if it's not explicitly provided.

Similarly, you can leave out Model, setting its properties on the Database.

Object definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. **Database** objects also have the following properties.

compatibilitylevel Currently, valid values are 1200, 1400. Lower compatibility levels use a different metadata engine.

readwritemode Enumerates the mode of the database. It's common to make a database read-only in high availability or scalability configurations. Valid values include `readWrite`, `readOnly`, or `readOnlyExclusive`.

Usage

Database objects are used in almost every command. See [Commands in Tabular Model Scripting Language \(TMSL\)](#) for a list. A **Database** object is a child of a **Server** object.

When creating, replacing, or altering a database object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Partial Syntax

Because this object definition is so large, only direct properties are listed. The [Model](#) object provides the bulk of the database definition. See [Model object \(TMSL\)](#) to learn more about how the object is defined.

```
JSON

"database": {
    "type": "object",
    "properties": {
        "name": {
            "type": "string"
        },
        "id": {
            "type": "string"
        },
        "description": {
            "type": "string"
        },
        "compatibilityLevel": {
            "type": "integer"
        },
        "readWriteMode": {
            "enum": [
                "readWrite",
                "readOnly",
                "readOnlyExclusive"
            ]
        },
        "model": {
            "type": "object",
            ...
        }
}
```

DataSources object (TMSL)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines a connection to a datasource used by the model either during import to add data to the model, or in pass through queries via DirectQuery mode. models in DirectQuery mode can only have one **DataSource** object.

How the **DataSource** object is defined in a model is determined by compatibility level:

- Tabular 1200 and lower models define a **Provider** object type.
- Tabular 1400 and higher models typically define a **Structured** object type, however, **Provider** object type is also supported.

Unless you are creating, replacing, or altering the datasource object itself, any datasource referenced in your script (such as in partition script) must be an existing **DataSource** object in your model.

Usage

DataSource objects are used in [Alter command \(TMSL\)](#), [Create command \(TMSL\)](#), [CreateOrReplace command \(TMSL\)](#), [Delete command \(TMSL\)](#), [Refresh command \(TMSL\)](#), and [MergePartitions command \(TMSL\)](#).

A **DataSource** object is a property of a model, but can also be specified as a property of a Database object given the one-to-one mapping between model and Database.

Partitions based on SQL queries also specify a **DataSource**, only with a reduced set of properties.

When creating, replacing, or altering a datasource object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Object definition

Common properties for the [DataSource Object](#) are described in the [MS-SSAS-T]: SQL Server Analysis Services Tabular Protocol.

Syntax

The JSON schema representation of a datasource object is defined in [dataSource](#) object in the [MS-SSAS-T]: SQL Server Analysis Services Tabular Protocol.

Model object (TMSL)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines a tabular model. There is one model per database, and only one database that can be specified in any given command. A Database object is the parent object.

Model definitions are too large to reproduce the entire syntax in one topic. For this reason, a partial syntax highlighting the main parts can be found below, with links to child objects.

Perhaps the best way to understand a model definition is to start with a tabular model that you know well. Use the **View Code** option in SQL Server Data Tools to view its definition. Remember to install a JSON editor so that you can view the code. You can get a JSON editor in Visual Studio by [downloading the Community edition](#) or other edition of Visual Studio.

Note

In any script, only one database at the time can be referenced. For any object other than database itself, the Database property is optional if you specify the model.

There is one-to-one mapping between a Model and a Database that can be used to deduce the Database name if it's not explicitly provided.

Similarly, you can leave out Model, setting its properties on the Database.

Object definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. **Model** objects also have the following properties.

storageLocation

The location on disk to place the model.

defaultMode

The default method for making data available in the partition.

default DataView

For models in DirectQuery mode, this property determines which partitions are used to run queries against the model. Valid values include Full and Sample.

culture

The culture to use for formatting.

collation

The collation sequence.

tables

The full collection of tables in the model, including partitions, columns, measures, KPIs, and annotations. See [Tables object \(TMSL\)](#) for details.

relationships

Specifies the relationship between each pair of tables, including properties that set filter direction and security. See [Relationships object \(TMSL\)](#) for details.

dataSources

One or more connections to external databases providing data to the model or used for pass through queries. See [DataSources object \(TMSL\)](#) for details.

roles

Objects that associate a database permission, member accounts, and optionally, security filters in DAX for custom access control.

Usage

Model objects contain an entire model. You need to specify either one Model and/or its parent Database object in most commands.

When creating, replacing, or altering a model object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Partial Syntax

Because this object definition is so large, only the first level properties are listed. See [Object Definitions in Tabular Model Scripting Language \(TMSL\)](#) for a list of child objects.

JSON

```
"model": {  
    "description": "Model object of a tabular database",

Partitions object (TMSL)

Article • 12/09/2022

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Defines a partition, or logical segmentation, of the table rowset. A partition consists of a Power Query M or SQL query used for importing data, for sample data in the modeling environment, or as a full data query for pass through query execution via DirectQuery.

Properties on the partition determine how the data is sourced for the table. In the object hierarchy, the parent object of a partition is a table object.

Object definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. **Partition** objects also have the following properties.

type

The type of partition. Valid values are numeric, and include the following:

- Query (1) – data in this partition is retrieved by executing a query against a **DataSource**. The **DataSource** must be a data source defined in the model.bim file.
- Calculated (2) – data in this partition is populated by executing a calculated expression.
- None (3) – data in this partition is populated by pushing a rowset of data to the server as part of the Refresh operation.

mode

Defines the query mode of the partition. Valid values are **import**, **DirectQuery**, or **default** (inherited). This value is required.

Expand table

Value	Description
Import	Indicates query requests are issued against the in-memory analytics engine storing imported data.
DirectQuery	Pass through query execution to an external relational database. DirectQuery mode uses partitions to provide sample data used during model design. When deployed

Value	Description
	on a production server, you should switch back to Full data view. Recall that DirectQuery mode requires one partition per table, and one data source per model.
default	Set this if you want to switch modes higher up the object tree, at the model or database level. When you choose default, the query mode will be either import or DirectQuery.

source

Identifies the location of the data to be queried. Valid values are **query**, **calculated**, or **none**. This value is required.

[\[+\] Expand table](#)

Value	Description
none	Used for import mode, where data is loaded and stored in memory.
query	For DirectQuery mode, this is a SQL query executed against the relational database specified in the model's DataSource . See DataSources object (TMSL) .
calculated	Calculated tables are sourced from an expression specified when the table is created. This expression is considered the source of the partition created for the calculated table.

dataview

For DirectQuery partitions, an additional **dataView** property further specifies whether the query that retrieves data is a sample or the full dataset. Valid values are **full**, **sample**, or **default** (inherited). As noted, samples are used only during data modeling and testing.

Usage

Partition objects are used in [Alter command \(TMSL\)](#), [Create command \(TMSL\)](#), [CreateOrReplace command \(TMSL\)](#), [Delete command \(TMSL\)](#), [Refresh command \(TMSL\)](#), and [MergePartitions command \(TMSL\)](#).

When creating, replacing, or altering a partition object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion. Read-write properties include name, description, mode, and source.

Examples

Example 1 - A simple partition structure of a table (not a fact table).

JSON

```
"partitions": [
    {
        "name": "Customer",
        "source": {
            "query": "SELECT [dbo].[Customer].* FROM [dbo].[Customer]",
            "dataSource": "SqlServer localhost FoodmartDB"
        }
    }
]
```

Example 2 - Partitioned fact data is typically based on a WHERE clause that creates non-overlapping partitions for data from the same table.

JSON

```
"partitions": [
    {
        "name": "sales_fact_2015",
        "source": {
            "query": "SELECT [dbo].[sales_fact_2015].* FROM [dbo].[sales_fact_2015] WHERE [dbo].[sales_fact_2015].[Quarter]=4",
            "dataSource": "SqlServer localhost FoodmartDB"
        }
    }
]
```

Example 3 - A calculated table based on a DAX expression.

JSON

```
"partitions": [
    {
        "name": "CalcTable1",
        "source": {
            "type": "calculated",
            "expression": "'Product Class'"
        }
    }
]
```

Full Syntax

Below is the schema representation of a partition object.

JSON

```
"partitions": {
    "type": "array",
    "items": {
        "description": "Partition object of Tabular Object Model (TOM)",
        "type": "object",
        "properties": {
            "name": {
                "type": "string"
            },
            "description": {
                "anyOf": [
                    {
                        "type": "string"
                    },
                    {
                        "type": "array",
                        "items": {
                            "type": "string"
                        }
                    }
                ]
            },
            "mode": {
                "enum": [
                    "import",
                    "directQuery",
                    "default"
                ]
            },
            "dataView": {
                "enum": [
                    "full",
                    "sample",
                    "default"
                ]
            },
            "source": {
                "anyOf": [
                    {
                        "description": "QueryPartitionSource object of Tabular Object Model (TOM)",
                        "type": "object",
                        "properties": {
                            "type": {
                                "enum": [
                                    "query",
                                    "calculated",
                                    "none"
                                ]
                            },
                            "query": {
                                "anyOf": [
                                    {
                                        "type": "string"
                                    }
                                ]
                            }
                        }
                    }
                ]
            }
        }
    }
}
```

Relationships object (TMSL)

Article • 04/10/2023

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines a relationship between a source and target table, with the ability to specify cardinality, and the direction of query and security filters.

Object definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. Relationship objects also have the following properties.

isActive

A Boolean that indicates whether the relationship is marked as Active or Inactive. An Active relationship is automatically used for filtering across tables. An Inactive relationship can be used explicitly by DAX calculations with the `USERELATIONSHIP` function.

`**crossFilteringBehavior` ** Indicates how relationships influence filtering of data. Valid values are:

- OneDirection (1) - The rows selected in the "To" end of the relationship will automatically filter scans of the table in the "From" end of the relationship.
- BothDirections (2) - Filters on either end of the relationship will automatically filter the other table.
- Automatic (3) - The engine will analyze the relationships and choose one of the behaviors by using heuristics.

joinOnDateBehavior

When joining two date time columns, indicates whether to join on date and time parts or on date part only.

- DateAndTime (1) - When joining two date time columns, join on date and time parts.
- DatePartOnly (2) - When joining two date time columns, join on date part only.

relyOnReferentialIntegrity

Unused; reserved for future use.

securityFilteringBehavior

An enumeration that indicates how relationships influence filtering of data when evaluating row-level security expressions. Valid values are as follows:

- OneDirection (1) - The rows selected in the "To" end of the relationship will automatically filter scans of the table in the "From" end of the relationship.
- BothDirections (2) - Filters on either end of the relationship will automatically filter the other table.

Usage

Relationship objects are used in [Alter command \(TMSL\)](#), [Create command \(TMSL\)](#), [CreateOrReplace command \(TMSL\)](#), and [Delete command \(TMSL\)](#).

When creating, replacing, or altering a relationship object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Full Syntax

Below is the schema representation of a relationship object.

```
JSON

"relationships": {
    "type": "array",
    "items": {
        "anyOf": [

Roles object (TMSL)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines a role on the model that specifies a collection of permissions. Role membership consists of Windows security principals. You can set filters on a role to restrict access to specific objects.

Object definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. **Role** objects also have the following properties.

modelPermission

Establishes a scope of permissions on a database. Valid values are none, read, readRefresh, refresh, and administrator.

members

Members consist of both a member name and ID, where member name is the alias or friendly name of a Windows security principal, and the ID is the security identifier. Both are specified in role definition.

tablePermissions

A table permission is a named object with permissions defined via a DAX expression. This property is optional, used to apply a security filter.

Usage

Role objects are used in [Alter command \(TMSL\)](#), [Create command \(TMSL\)](#), [CreateOrReplace command \(TMSL\)](#), and [Delete command \(TMSL\)](#).

A **Role** object is a property of a Model, but can also be specified as a property of a Database object given the one-to-one mapping between Model and Database.

When creating, replacing, or altering a role object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Full Syntax

Below is the schema representation of a role object of a model.

JSON

```
"roles": {
    "type": "array",
    "items": {
        "description": "ModelRole object of Tabular Object Model (TOM)",
        "type": "object",
        "properties": {
            "name": {
                "type": "string"
            },
            "description": {
                "anyOf": [
                    {
                        "type": "string"
                    },
                    {
                        "type": "array",
                        "items": {
                            "type": "string"
                        }
                    }
                ]
            },
            "modelPermission": {
                "enum": [
                    "none",
                    "read",
                    "readRefresh",
                    "refresh",
                    "administrator"
                ]
            },
            "annotations": {
                "type": "array",
                "items": {
                    "description": "Annotation object of Tabular Object Model (TOM)",

Tables object (TMSL)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services
 Fabric/Power BI Premium

Defines the tables contained in a model. Tables in a model are either bound to tables in an external database from which data is imported or queried, or a calculated table constructed from a DAX expression. Within a table, one or more **Partition** objects describe the source of the data. Between tables, a **Relationship** object specifies the cardinality, filter direction, and other properties of the relationship.

Object Definition

All objects have a common set of properties, including name, type, description, a properties collection, and annotations. **Table** objects also have the following properties.

dataCategory

Specifies the type of Table, usually left unspecified. Valid values include 0 - UNKNOWN, 1 - TIME, 2 - MEASURE, 3 - OTHER, 5 - QUANTITATIVE, 6- ACCOUNTS, 7 - CUSTOMERS, 8- PRODUCTS, 9 - SCENARIO, 10- UTILITY, 11 - CURRENCY, 12 - RATES, 13 - CHANNEL, 4 - PROMOTION, 15 - ORGANIZATION, 16 - BILL OF MATERIALS, 17 – GEOGRAPHY.

isHidden

A Boolean that indicates whether the table is treated as hidden by client visualization tools.

True if the Table is treated as hidden; otherwise false.

columns

Represents a column in a Table. It is a child of a Table object. Each column has a number of properties defined on it that influence how client applications visualize the data in the column.

measures

Represents a value that is calculated based on an expression. It is a child of a Table object.

hierarchies

Represents a collection of levels that provide a logical hierarchical drilldown path for client applications. It is a child of a Table object.

Usage

Table objects are used in [Alter command \(TMSL\)](#), [Create command \(TMSL\)](#), [CreateOrReplace command \(TMSL\)](#), [Delete command \(TMSL\)](#), [Refresh command \(TMSL\)](#), and [MergePartitions command \(TMSL\)](#).

When creating, replacing, or altering a table object, specify all read-write properties of the object definition. Omission of a read-write property is considered a deletion.

Condensed Syntax

Table object definitions are complex. This syntax collapses interior properties and objects to give you a high-level look at the main parts.

JSON

```
"tables": {  
    "type": "array",  
    "items": {  
        "description": "Table object of Tabular Object Model (TOM)",  
        "type": "object",  
        "properties": {  
            "dataCategory": { },  
            "description": { },  
            "isHidden": { },  
            "partitions": { },  
            "annotations": { },  
            "columns": { },  
            "measures": { },  
            "hierarchies": { },  
            "name": { },  
            "type": "string"  
        }  
    }  
}
```

Full Syntax

Below is the schema representation of a tables object of a model. To reduce the size of this definition, Partition objects are described elsewhere. See [Partitions object \(TMSL\)](#).

JSON

```
"tables": {  
    "type": "array",  
    "items": {  
        "description": "Table object of Tabular Object Model (TOM)",  
        "type": "object",  
        "properties": {  
            "name": { },  
            "type": "string",  
            "dataCategory": { },  
            "isHidden": { },  
            "partitions": { },  
            "annotations": { },  
            "columns": { },  
            "measures": { },  
            "hierarchies": { }  
        }  
    }  
}
```

Tabular Model Definition Language (TMDL)

Article • 01/03/2024

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services
 Fabric/Power BI Premium

Tabular Model Definition Language (TMDL) is an object model definition syntax for tabular data models at compatibility level 1200 or higher.

Key elements of TMDL include:

- Full compatibility with the entire [Tabular Object Model \(TOM\)](#). Every TMDL object exposes the same properties as TOM.
- Text-based and optimized for human interaction and readability. TMDL uses a grammar syntax similar to YAML. Each TMDL object is represented in text with minimal delimiters and uses indentation to demark parent-child relationships.
- Better editing experience, especially on properties with embed expressions from different content-types, like Data Analysis Expression (DAX) and M.
- Better for collaboration because of its folder representation where each model object has an individual file representation, making it more source control friendly.

An important aspect of TMDL is use of whitespace indentation to denote a TOM object structure. The following example shows how easy it is to represent a tabular model when using TMDL:

```
tmld

database Sales
    compatibilityLevel: 1567

model Model
    culture: en-US

table Sales

    partition 'Sales-Partition' = m
        mode: import
        source =
            let
                Source = Sql.Database(Server, Database)
            ...
        measure 'Sales Amount' = SUMX('Sales', 'Sales'[Quantity] * 'Sales'[Net
Price])
```

```

formatString: $ #,##0

column 'Product Key'
    dataType: int64
    isHidden
    sourceColumn: ProductKey
    summarizeBy: None

column Quantity
    dataType: int64
    isHidden
    sourceColumn: Quantity
    summarizeBy: None

column 'Net Price'
    dataType: int64
    isHidden
    sourceColumn: "Net Price"
    summarizeBy: none

table Product

partition 'Product-Partition' = m
    mode: import
    source =
        let
            Source = Sql.Database(Server, Database),
            ...
        end

    column 'Product Key'
        dataType: int64
        isKey
        sourceColumn: ProductKey
        summarizeBy: none

relationship cdb6e6a9-c9d1-42b9-b9e0-484a1bc7e123
    fromColumn: Sales.'Product Key'
    toColumn: Product.'Product Key'

role Role_Store1
    modelPermission: read

    tablePermission Store = 'Store'[Store Code] IN {1,10,20,30}

expression Server = "localhost" meta [IsParameterQuery=true, Type="Text",
IsParameterQueryRequired=true]

expression Database = "Contoso" meta [IsParameterQuery=true, Type="Text",
IsParameterQueryRequired=true]

```

TMDL folder structure

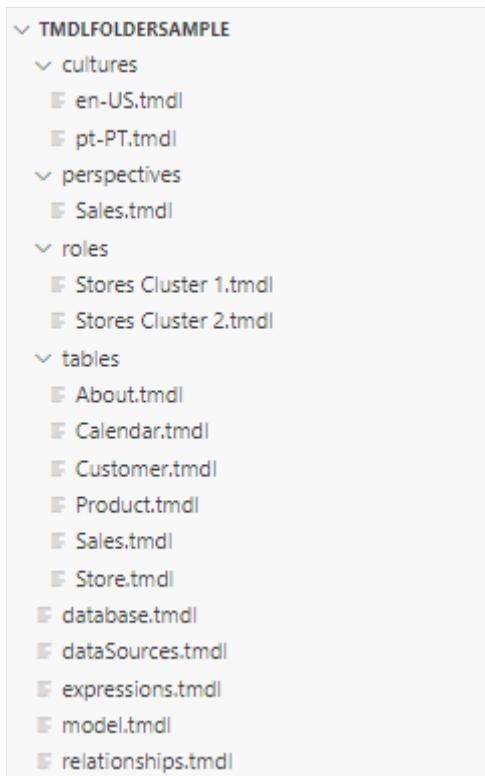

Unlike TMSL, TMDL uses a folder structure. The default folder structure has only one level of *sub-folders*, all with .tmdl files inside:

- cultures
- perspectives
- roles
- tables

And *root files* for:

- database
- model
- relationships
- expressions
- datasources

Here's an example of a TMDL folder:

Definitions include:

- One file for database definition.
- One file for model definition.
- One file for *all* datasources in the model.
- One file for *all* expressions in the model.
- One file for *all* relationships in the model.
- One file for *each* culture linguistic schema.
- One file for *each* perspective.

- One file for *each* role.
- One file for *each* table.
- All inner metadata properties of tables (Column, Hierarchies, Partitions,...) metadata lives in the parent table TMDL file.

TMDL API

Similar to [Tabular Model Scripting Language \(TMSL\)](#), there's a class to handle TMDL Serialization. For TMDL, the class is [TmdlSerializer](#), under the [Microsoft.AnalysisServices.Tabular](#) namespace.

The [TmdlSerializer](#) class exposes methods to serialize and deserialize TMDL documents:

Folder Serialization

```
public static void SerializeDatabaseToFolder (Database database, string path)
```

- Receives a TOM database object and the TMDL output path.
- Serializes the TOM database into a TMDL folder representation.

[Learn more about how to serialize to a folder.](#)

```
public static Database DeserializeDatabaseFromFolder (string path)
```

- Receives a full path to a TMDL folder.
- Returns the TOM database object representation of the TMDL folder.

[Learn more about how to deserialize from folders.](#)

String Serialization

```
public static string SerializeObject (MetadataObject object, bool qualifyObject = true)
```

- Receives a TOM object and returns its TMDL text representation.

[Learn more about how to serialize an object to a string.](#)

Stream Serialization

You can serialize/deserialize TMDL to/from streams, allowing you to convert a TOM object into byte streams for storage, transmission, and interoperability across platforms.

The Stream API also allows you to control which TMDL documents are loaded and which TMDL documents are outputted.

TMDL Stream serialization is handled by the [MetadataSerializationContext](#) class.

Learn more [about how to serialize to/from TMDL using streams](#).

TMDL language

Object declaration

Except for Server object, TMDL exposes the entire TOM *Database* object tree in the [Microsoft.AnalysisServices.Tabular namespace](#).

A TMDL object is declared by specifying the TOM object type followed by its name. In the following code example, each object type: `model`, `table`, `column` is followed by an object name.

```
tmld

model Model
    culture: en-US

table Sales

    measure Sales = SUM(...)
        formatString: $ #,##0

    column 'Customer Key'
        datatype: int64
        sourceColumn: CustomerKey
```

Objects like `partition` or `measure` have [default properties](#) that can be assigned after the equals (=) delimiter in the same line of the object declaration or in the following line for a multi-line [expression](#):

```
tmld

table Sales

    partition Sales-Part1 = m
        mode: import
        ...

    measure Sales = SUM(...)
```

```

formatString: $ #,##0

measure 'Sales (ly)' =
    var ly = ...
    return ly
formatString: $ #,##0

```

The TMDL object name must be enclosed in single quotes ('') if it includes any of the following characters:

- Dot (.)
- Equals (=)
- Colon (:)
- Single Quote (')
- Whitespace ()

If an object name contains single quotes (''), use two single quotes to escape it.

Object Properties

Object properties are specified after the object declaration or object default property multi-line expression. Object property values are specified following the colon (:) delimiter. For example:

```

tmldl

table Sales
    lineageTag: e9374b9a-faee-4f9e-b2e7-d9aafb9d6a91

        column Quantity
            dataType: int64
            isHidden
            isAvailableInMdx: false
            sourceColumn: Quantity

        measure 'Sales Amount' =
            var result = SUMX(...)
            return result
        formatString: $ #,##0
        displayFolder: " My ""Amazing"" Measures"

```

The following rules apply to property values:

- Value must be in the same line following the colon and cannot have multiple lines.
- Text property values

- Leading and trailing Double-quotes are optional and automatically stripped during serialization.
- Must be enclosed in double quotes ("") if the text contains trailing or leading whitespace.
- When enclosed in double quotes, if the value contains double quotes, use two double quotes to escape them (see `displayFolder` property in the code example above).
- **Boolean properties** can be set by using standard key/value pair syntax, like with the `'isAvailableInMdx'` property in the previous example. They can also be set by using a shortcut syntax where only the property name is declared and `true` is implied. See, for example, the `'isHidden'` property in the previous example.

Named object references

Some object properties hold references to other model objects, for example:

- Column reference in hierarchy levels.
- `sortByColumn` reference in each table column.
- Table/column/measure reference in perspectives.

In TMDL, references are made using the object name and follow the same escaping and single-quote ('') enclosing requirements of object declaration. In the following code example, you see object properties that hold a reference to another object:

```
column.sortByColumn, level.column, perspectiveMeasure.measure and
perspectiveTable.table.
```

```
tmdl

table Product

    column Category
        sortByColumn: 'Category Order'

    hierarchy 'Product Hierarchy'

    level Category
        column: Category

perspective Product

perspectiveTable Product
```

```
perspectiveMeasure '# Products'
```

If needed to reference a fully qualified name, TMDL uses *dot* notation to reference an object, for example: 'Table 1'. 'Column 1'

Child objects

The TOM object tree contains child objects in many places and at different levels. For example:

- A model object contains table, role, and expression objects.
- A table object contains column, measure, and hierarchy objects.

TMDL doesn't declare child collections explicitly. Instead, all applicable child elements within the scope of their respective parent implicitly make up the elements of the corresponding collection. For example, all column elements within the scope of a particular table become elements of the columns collection of that table in TOM, like shown here:

```
tmdl  
  
table Sales  
  
    measure 'Sales Amount' = SUMX('Sales', [Quantity] * [Net Price])  
  
    measure 'Total Quantity' = SUM('Sales'[Quantity])  
  
    measure 'Sales Amount YTD' = TOTALYTD([Sales Amount], 'Calendar'[Date])
```

Child objects don't have to be contiguous. For example, you can declare columns and measures in any order and intermingled.

Default properties

Some object types have a default property that most of the time are treated like [expressions](#). The default property is object type specific. Where applicable, the property value or expression is specified following the equals (=) delimiter - after the section declaration.

Supported syntax:

- The value is specified on the same line as the section header.

- The value is specified as a multi-line expression following the section header.

In the following code example, measure `Sales Amount` and partition `Sales-Partition1` are single line and measure `Quantity` is multi-line:

```
tmld

table Sales

    measure 'Sales Amount' = SUM(...)
        formatString: $ #,##0

    measure Quantity =
        var result = SUMX (...)

        return result
        formatString: #,##0

    partition Sales-Partition1 = m
mode: import
source =
let
...
in
finalStep
```

Expressions

There are object properties that, while being a text property in TOM, get special parsing in TMDL. The entire text is read verbatim because it can include special characters like quotes or square brackets in M or DAX expressions. Expressions could be multi-line or single-line. If multi-line, they must be located in the line immediately following the property or object declaration.

An expression value in TMDL is specified following a equals (=) delimiter, like in the following example:

```
tmld

table Table1

    partition 'partition 1' = m
        mode: import
        source =
        let
        ...
        in
        finalStep
```

```

measure Measure1 = SUM(...)

measure Measure2 =
    var result = SUMX (
        ...
    )
    return result
formatString: $ #,##0

```

The following special rules apply to expressions:

- Multi-line expressions must be indented one level deeper to the parent object properties and the entire expression must be within that indentation level.
- All outer indentation whitespaces are stripped beyond the indented level of the parent object.
- Vertical whitespaces (blank lines without whitespaces) are allowed and are considered part of the expression.
- Trailing blank lines and whitespaces are removed.
- To enforce a different indentation or to preserve trailing blank lines or whitespaces, use the three backticks (``) enclosing.
- By default, TMDL serializer will enclose with backticks if the expression value contains anything that could cause a modification on roundtrip (for example, trailing whitespaces, blank lines with whitespaces).

Expressions enclosed with three backticks (``) are read verbatim including indentation, blank lines and whitespaces. The delimiter should be applied immediately following the equal sign (=) and the line following the expression and cannot have anything after it, like in the following example:

```

tmdl

table Table1

partition partition1 = m
    mode: import
    source = ```
        let
        ...
        in
            finalStep
        ```

measure Measure1 = ``
 var myVar = Today()
 ...

```

```
 return result
 ...
```

Using the three backticks (``) delimiter is optional and only required in unique situations. For most situations, using correct indentation and object declaration ensures correct parsing of whatever expression you add to the property.

When the expression is enclosed within backticks, the following rules apply:

- Everything between three backticks (``) is considered part of the multi-block expression and TMDL indentation rules aren't applied. The end delimiter determines the indentation within the expression.
- Relative indentation within the expression is retained. The end delimiter (``) determines the expression left boundary (see 'Measure1' in the previous example).

The following properties are treated as expressions:

[Expand table](#)

Object Type	Property	Expression language
Measure	Expression	DAX
MPartitionSource	Expression	M
CalculatedPartitionSource	Expression	DAX
QueryPartitionSource	Query	NativeQuery
CalculationItem	Expression	DAX
BasicRefreshPolicy	SourceExpression, PollingExpression	M
KPI	StatusExpression, TargetExpression, TrendExpression	DAX
LinguisticMetadata	Content	XML or Json
JsonExtendedProperty	Value	Json
FormatStringDefintion	Expression	DAX
DataCoverageDefinition	Expression	DAX
CalculationGroupExpression	Expression	DAX
NamedExpression	Expression	DAX

Object Type	Property	Expression language
DetailRowsDefinition	Expression	DAX
TablePermission	FilterExpression	DAX
CalculatedColumn	Expression	DAX

## Default properties by object type

The following table shows default property and expression language by object type:

Any Custom JSON Property (for example, DataAccessOptions)	JSON Document	Json
LinguisticMetadata	Content	Json

## Descriptions

TMDL provides first class support for descriptions. For model documentation purposes, best practice is to provide descriptions for each TOM object. TMDL treats descriptions as a special property with explicit syntax support. Following the examples from many other languages, descriptions are specified on top of each object declaration using triple-slash (///) syntax.

No whitespace is allowed between the description block end and the object type token.

Descriptions can be split across multiple lines. The TMDL serializer breaks object descriptions into multiple lines to keep emitted document lines under the maximum length. The default maximum length is 80 characters.

```
tmld

/// Table Description
table Sales

 /// This is the Measure Description
 /// One more line
 measure 'Sales Amount' = SUM(...)
 formatString: #,##0
```

## Partial declaration

TMDL doesn't force object declaration in the same document. It is, however, similar to [C# partial classes](#) where it's possible split the object definition between multiple files. For example, you can declare a table definition in a [table].tmld file and then have all the measures from all tables defined in a single [measures].tmld file, as shown here:

```
tmdl

```

To avoid a parsing error, the same property can't be declared twice. For example, declaring two measures with same name for the same table in two different TMDL documents results in an error.

## Object references

You can reference another TMDL object using the **ref** keyword followed by the object type and name.

For example, if you serialize a Column object using the string serialization API, the outcome will be:

```
tmdl

ref table Table1
 column Column1
 datatype: int64
 sourceColumn: Column1
```

## Deterministic collection ordering

The **ref** keyword is also used to define and preserve the collection ordering on TOM <> TMDL roundtrips. It's particularly important to avoid source control diff's on TMDL objects that get serialized into individual files: Tables, Roles, Cultures and Perspectives.

The **ref** keyword is used on the parent object TMDL file to declare the item ordering from TOM:

```
tmdl

model Model

ref table Calendar
ref table Sales
```

```
ref table Product
ref table Customer
ref table About

ref culture en-US
ref culture pt-PT

ref role 'Stores Cluster 1'
ref role 'Stores Cluster 2'
```

The following rules are applied:

- During TMDL Deserialization:
  - Objects referenced in TMDL but with missing TMDL file, are ignored.
  - Objects not referenced but with existing TMDL file, are appended to the end of the collection.
- During TMDL Serialization:
  - All collection objects in TOM are referenced using the **ref** keyword.
  - Collections with only one item don't emit a ref.
  - Blank lines are not emitted between ref's if the same object type.

## Property value delimiters

There are only two delimiters/symbols to assign a property value:

- Equals (=)
  - Used at object declaration with **default property** (multi and single line)
  - Used at every **expression property**, for example, partition.expression
- Colon (:)
  - Used for every non-expression **property value**. Including properties that hold model references.

## Indentation

TMDL uses strict whitespace indentation rules for denoting structure of the TOM hierarchy. A TMDL document uses a default single **tab** indentation rule.

Each object can have three levels of indentation:

- Level 1 - Object Declaration
  - Level 2 - Object Properties
  - Level 3 - Object property multi-line expressions

Within a TMDL document, indentation is applied in the following cases:

- Between an object section header and the object's properties (table -> properties).

```
tmld

```

- Between an object and its child objects (table -> measures).

```
tmld

```

- Between an object and its multi-line expressions (table -> measure -> expression).

```
tmld

```

- Multi-line expressions must be indented one level deeper than object properties and the entire expression must be within that indentation level (see [expressions](#)).

Database and direct child objects of Model don't need to be indented because they are implicitly assumed nested under the root Model or Database:

- model
- tables
- shared expressions
- roles
- cultures
- perspectives
- relationships
- data sources
- query groups
- model-level annotations

- model-level extended properties

Not following these indentation rules generates a parsing error.

## Whitespace

TMDL by default applies the following rules to whitespace within property and expression values, when not enclosed within backticks (`) or double-quotes ("):

- On property values, leading and trailing whitespaces are trimmed.
- On expressions, whitespace lines at the end of expressions are dropped.
- Whitespace lines are trimmed to empty lines (no spaces/tabs).

## Casing

By default TMDL API on serialize/write use **camelCase**, applied to:

- Object types
- Keywords
- Enum values

On deserialize/read, TMDL API is case insensitive.

# Get started with TMDL

Article • 08/05/2024

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services  
 Fabric/Power BI Premium

Before getting started with this article, be sure to thoroughly understand concepts described in [Tabular Model Definition Language \(TMDL\) overview](#).

The easiest way to explore TMDL is to reference the Analysis Services Management Objects (AMO) [Nuget package](#) and use the TMDL API methods to serialize and deserialize to and from TMDL.

[Get the Nuget packages](#)

## Get a TMDL model representation

The following code example shows how to get a TMDL model representation of a semantic model in a Power BI Premium workspace:

```
c#

var workspaceXmla = " <Workspace XMLA address>";
var datasetName = "<dataset name>";
var outputPath = System.Environment.CurrentDirectory;

using (var server = new Microsoft.AnalysisServices.Tabular.Server())
{
 server.Connect(workspaceXmla);

 var database = server.Databases.GetByName(datasetName);

 var destinationFolder = $"{outputPath}\\{database.Name}-tmdl";

 Microsoft.AnalysisServices.Tabular.TmdlSerializer.SerializeDatabaseToFolder(
 database.Model, destinationFolder);
}
```

The output is a folder with a TMDL representation of the model, like this:

▼ TMDLFOLDERSAMPLE
▼ cultures
■ en-US.tmdl
■ pt-PT.tmdl
▼ perspectives
■ Sales.tmdl
▼ roles
■ Stores Cluster 1.tmdl
■ Stores Cluster 2.tmdl
▼ tables
■ About.tmdl
■ Calendar.tmdl
■ Customer.tmdl
■ Product.tmdl
■ Sales.tmdl
■ Store.tmdl
■ database.tmdl
■ dataSources.tmdl
■ expressions.tmdl
■ model.tmdl
■ relationships.tmdl

After serialization into a folder, use a text-editor to edit the TMDL files. For example, by using Visual Studio Code we can add a new measure, **[Sales Amount (Computers)]**:

```
tmld

/// Sales data for year over year analysis
table Sales

 partition 'Sales-Part1' = m
 mode: Import
 source =
 let
 ...
 in
 #"Filtered Rows1"

 measure 'Sales Amount' = SUMX('Sales', [Quantity] * [Net Price])
 formatString: $ #,##0

 measure 'Sales Amount (Computers)' = CALCULATE([Sales Amount],
 'Product'[Category] = "Computers")
 formatString: $ #,##0
```

For a better experience you can install [Visual Studio Code TMDL language extension](#).

## Deploy a TMDL model representation

The following code example shows how to deploy a TMDL model representation of the model to a Power BI Premium workspace:

```
c#

var xmlaServer = "<Workspace XMLA address>";

var tmdlFolderPath = $"{System.Environment.CurrentDirectory}\\Contoso-tmdl";

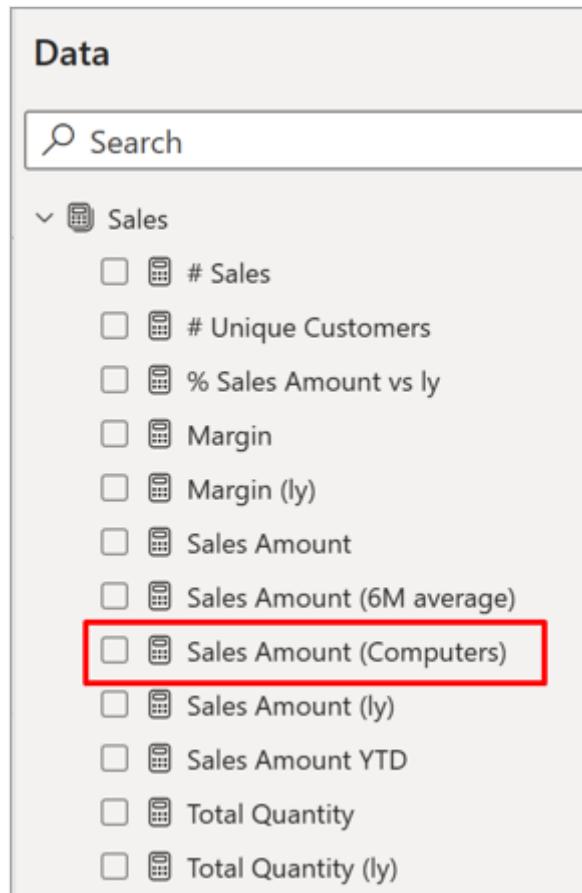

var model =
 Microsoft.AnalysisServices.Tabular.TmdlSerializer.DeserializeModelFromFolder
(tmldFolderPath);

using (var server = new Microsoft.AnalysisServices.Tabular.Server())
{
 server.Connect(xmlaServer);

 using (var remoteDatabase = server.Databases[model.Database.ID])
 {
 model.CopyTo(remoteDatabase.Model);

 remoteDatabase.Model.SaveChanges();
 }
}
```

When executed, the new measure is deployed to the model.

The screenshot shows the 'Data' view in Power BI. A search bar at the top contains the text 'Search'. Below it, a tree view shows a folder named 'Sales' expanded. Inside the 'Sales' folder, there are several measures listed as checkboxes. One measure, 'Sales Amount (Computers)', is highlighted with a red rectangular box around its checkbox and text. Other measures visible include '# Sales', '# Unique Customers', '% Sales Amount vs ly', 'Margin', 'Margin (ly)', 'Sales Amount', 'Sales Amount (6M average)', 'Sales Amount (ly)', 'Sales Amount YTD', 'Total Quantity', and 'Total Quantity (ly)'. The background of the Data view is light gray, and the overall interface is clean and modern.

# Handling TMDL serialization errors

When an error is detected in TMDL serialization methods, besides throwing a few common .NET exceptions like `ArgumentException` and `InvalidOperationException`, TMDL-specific exceptions are also returned.

- `TmdlFormatException` is thrown if the TMDL text is not a valid syntax. For example, invalid keyword or indentation.
- `TmdlSerializationException` is thrown if the TMDL text is valid, but violates the TOM metadata logic. For example, type of value does not match the expected type.

In addition to exception details, the following is included:

- `document path`: Path to the TMDL file with errors.
- `line number`: line number with errors.
- `line text`: line text with errors.

Code example handling `TmdlFormatException`:

C#

```
try
{
 var tmdlPath = "<TMDL Folder Path>";

 var model =
Microsoft.AnalysisServices.Tabular.TmdlSerializer.DeserializeDatabaseFromFolder(tmdlPath);
}
catch (Microsoft.AnalysisServices.Tabular.Tmdl.TmdlFormatException ex)
{
 Console.WriteLine($"Error on Deserializing TMDL '{ex.Message}', document
path: '{ex.Document}' line number: '{ex.Line}', line text:
'{ex.LineText}'");

 throw;
}
```

## Object text serialization

The following code example shows how to serialize a column into TMDL:

C#

```
var output =
Microsoft.AnalysisServices.Tabular.TmdlSerializer.SerializeObject(model.Tables["Product"].Columns["ProductKey"], qualifyObject: true);

Console.WriteLine(output);
```

Output:

```
tmdl

ref table Product

column ProductKey
 dataType: int64
 isKey
 formatString: 0
 isAvailableInMdx: false
 lineageTag: 4184d53e-cd2d-4cbe-b8cb-04c72a750bc4
 summarizeBy: none
 sourceColumn: ProductKey

annotation SummarizationSetBy = Automatic
```

## Stream serialization

The following code example shows how to serialize a semantic model to a single text variable:

C#

```
var output = new StringBuilder();

foreach (Microsoft.AnalysisServices.Tabular.Serialization.MetadataDocument
document in model.ToTmdl())
{
 using (TextWriter writer = new StringWriter(output))
 {
 document.WriteTo(writer);
 }
}

Console.WriteLine(output.ToString());
```

The following code example shows how to deserialize from TMDL, excluding the roles:

C#

```
var context =
Microsoft.AnalysisServices.Tabular.Serialization.MetadataSerializationContext
t.Create(MetadataSerializationStyle.Tmdl);

var files = Directory.GetFiles("[TMDL Directory Path]", "*.tmdl",
SearchOption.AllDirectories);

foreach (var file in files)
{
 if (file.Contains("/roles/"))
 continue;

 using (TextReader reader = File.OpenText(file))
 {
 context.ReadFromDocument(file, reader);
 }
}

var model = context.ToModel();
```

# TMDL Reference - Objects overview

Article • 08/05/2024

Applies to: SQL Server 2016 and later Analysis Services Azure Analysis Services  
 Fabric/Power BI Premium

All TMDL objects have an exact match with their **Tabular Object Model (TOM)** properties, except for [Translations](#) and [Role members](#).

For example, here's a TMDL calculated column representation:

```
tmld

table Calendar

column 'Date (Year-Month)' = DATE([Year], [Month],1)
 dataType: dateTime
 formatString = mmm yyyy
 lineageTag: 0e65a7a5-6c15-437d-8333-10653d8d673f
 summarizeBy: none

 annotation SummarizationSetBy = automatic
```

Each of the preceding TMDL properties maps to the [CalculatedTableColumn](#) class properties as follows:

- [expression](#) - Default Property
- [dataType](#)
- [formatString](#)
- [lineageTag](#)
- [summarizeBy](#)

## Translations in TMDL

In TOM, translations are represented as a collection of [ObjectTranslation](#) objects. For optimal interaction and readability, TMDL breaks the principle of alignment with the TOM object tree and replicates the model hierarchy underneath each culture as virtual TMDL properties.

For each object, translations can be added for the following properties:

Expand table

Property	Description
caption	Translated table/column/measure/... title that appears in any client application supporting visualizations of a Tabular model.
description	Translated description appears as model information.
displayFolder	translated column/measure/hierarchy display folder used by client applications to organize content.

The following code example is a TMDL translation for Portuguese culture (pt-PT):

```

tmdl

culture pt-PT
translations
model Model
caption: Modelo
description: Modelo
table Calendar
caption: Calendário
table Sales
caption: Vendas
measure 'Sales Amount'
caption: Total de Vendas
displayFolder: Métricas Base
measure 'Sales Amount (LY)'
caption: Total Vendas (Ano Anterior)
displayFolder: Métricas Base
measure 'Sales Amount (YTD, LY)'
displayFolder: Métricas Base
table Product
caption: Produto
description: Tabela de Produto
column Product
caption: Produto
description: Coluna de Produto
column ProductKey
caption: Chave de Produto
column Weight
caption: Peso
hierarchy 'Product Hierarchy'
caption: Hierarquia de Produto
table Customer
caption: Cliente
column Address
caption: Morada
table Store
caption: Loja
column StoreKey
caption: Código de Loja

linguisticMetadata =

```

```
{
 ...
}
```

## Role members in TMDL

Role members could number in the hundreds or thousands, so serializing each member as a separate object using its native TOM representation ([WindowsModelRoleMember](#) or [ExternalModelRoleMember](#)) would be unreadable. To optimize for interaction and readability, TMDL breaks the principle of alignment with TOM object tree, and optimizes role members representation for the most common scenario: Microsoft Entra ID (formerly known as Azure AD) and Windows Identity.

The following rules are applied:

- Member ID isn't serialized and assumes the same value as name
- Blank lines between members aren't emitted
- Members are emitted in the end after permissions

Default property of the member determines the member type:

[+] [Expand table](#)

Default Property	Description
Value	
user	ExternalModelRoleMember - IdentityProvider = AzureAD, RoleMemberType = User
group	ExternalModelRoleMember - IdentityProvider = AzureAD, RoleMemberType = Group
auto	ExternalModelRoleMember - IdentityProvider = AzureAD, RoleMemberType = Auto
activeDirectory	WindowsModelRoleMember

The following code example is a TMDL role with `ExternalModelRoleMembers` members:

```
tmdl

role 'StoreRole'
 modelPermission: read
```

```
tablePermission Store = 'Store'[Store Code] IN {"1","2","4"}

member 'user1@company.com'
member 'group@domain.com' = group
member 'user2@company.com' = auto
member user1FromCustomProvider
 identityProvider = customProviderName
member group1FromCustomProvider
 identityProvider = customProviderName
```

The following code example is a TMDL role with `WindowsModelRoleMember` members:

tmdl

```
role 'StoreRole'
modelPermission: read

tablePermission Store = 'Store'[Store Code] IN {"1","2","4"}

member company\user1 = activeDirectory
member company\group = activeDirectory
```

# TMDL scripts

Article • 01/14/2025

TMDL scripts enable you to apply an action to a semantic model, which could be a change or operation. A TMDL script has two parts:

- A *command*, which is required and should be declared at the top of the TMDL script.
- One or more *semantic model objects* using TMDL language definition or reference.

Syntax:

```
tmld
<TMDL Command name>
 <TMDL object>
 [<TMDL object>]
```

## CreateOrReplace command

Creates or replaces the specified semantic model objects and all the descendants. Existing objects are replaced with a new definition.

The order of TMDL objects inside the *createOrReplace* command is not important.

The semantics of TMDL language are applied to objects within the *createOrReplace* command. For example, it's possible to split the object definition into multiple segments, however the same property can't be declared more than once. You can [learn more about the TMDL language](#).

## Example

Create or replace the measure # *Products (with Sales)* from the table *Sales* and the full definition of the table *Product*:

```
tmld
createOrReplace
 ref table Sales
 measure '# Products (with Sales)' = DISTINCTCOUNT('Sales'[ProductKey])
```

```
formatString: #,##0

table Product

measure '# Products' = COUNTROWS('Product')
 formatString: #,##0

column Product
 dataType: string
 isDefaultLabel
 summarizeBy: none
 sourceColumn: Product

column Category
 dataType: string
 summarizeBy: none
 sourceColumn: Category

partition Product-partition = m
 mode: import
 source =
 let
 Source = #"RAW-Product",
 #"Renamed Columns" = Table.RenameColumns(Source,
 {"Product Name", "Product"})
 in
 #"Renamed Columns"
```

## Considerations and limitations

Only one command verb per script execution is supported.

# Analysis Management Objects (AMO)

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Analysis Management Objects (AMO) is a library of programmatically accessed objects that enables an application to manage an Analysis Services instance.

If you are programming for Azure Analysis Services, SQL Server Analysis Services, or Power BI Premium tabular models at 1200 or higher compatibility level, use the [Tabular Object Model \(TOM\)](#). TOM is an extension of the Analysis Services Management Object (AMO) client library.

This section explains AMO concepts, focusing on major objects, how and when to use them, and the way they are interrelated. For more information about specific objects or classes, see:

- [Microsoft.AnalysisServices Namespace](#), for reference documentation.
- [Analysis Services Management Objects \(AMO\)](#), as a Bing.com general search.

Beginning with SQL Server 2016, AMO is refactored into multiple assemblies. Generic classes such as Server, Database, and Roles are in the [Microsoft.AnalysisServices.Core Namespace](#). Multidimensional-specific APIs remain in [Microsoft.AnalysisServices Namespace](#).

Custom scripts and applications written against earlier versions of AMO will continue to work with no modification. However, if you have script or applications that target SQL Server 2016 or later specifically, or if you need to rebuild a custom solution, be sure to add the new assembly and namespace to your project.

# AMO concepts and object model

Article • 10/31/2023

Applies to: ✓ SQL Server Analysis Services ✓ Azure Analysis Services ✖  
Fabric/Power BI Premium

This article describes Analysis Management Objects (AMO), how AMO is related to other tools and libraries provided in the architecture of Analysis Services, and a conceptual explanation of all major objects in AMO.

AMO is a complete collection of management classes that can be used programmatically, under the namespace of [Microsoft.AnalysisServices](#), in a managed environment. The classes are included in the AnalysisServices.dll file, which is usually found where setup installs the files, under the folder \100\SDK\Assemblies\. To use the AMO classes, include a reference to this assembly in your projects.

By using AMO you can create, modify, and delete objects such as cubes, dimensions, mining structures, and databases; over all these objects, actions can be performed from your application in the .NET Framework. You can also process and update the information stored in databases.

## AMO in the Analysis Services architecture

By design, AMO is only intended for object management and not for querying data. If the user needs to query data from a client application, the client application should use [ADOMD.NET](#).

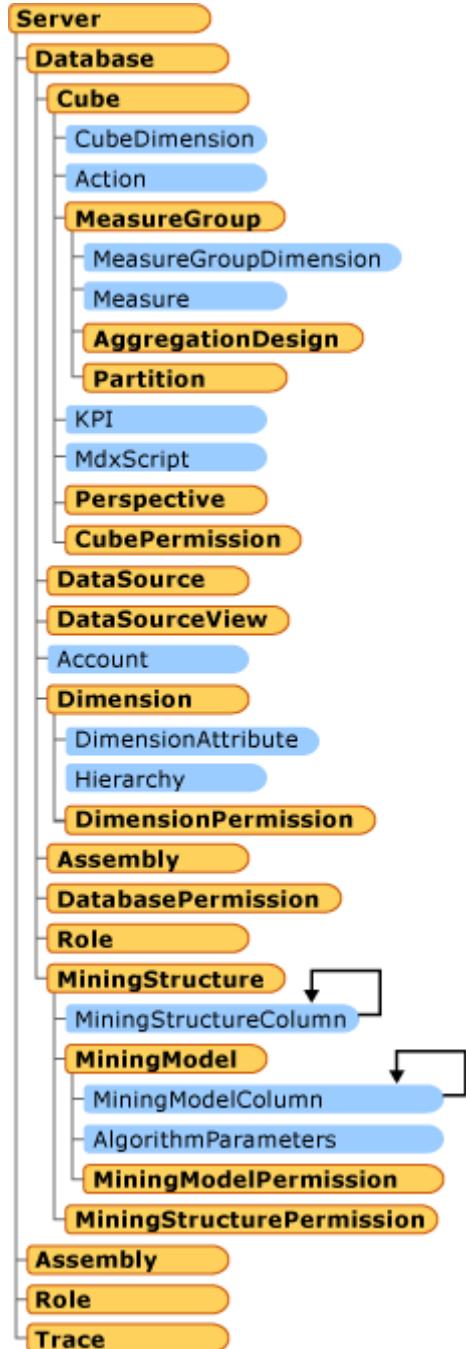

## AMO architecture

AMO is a complete library of classes designed to manage an Analysis Services instance from a client application in managed code under the .NET Framework version 2.0 and higher.

The AMO library of classes is designed as a hierarchy of classes, where certain classes must be instantiated before others in order to use them in your code. There are also auxiliary classes that can be instantiated at any time in your code, but you will probably have instantiated one or more of the hierarchy classes before using any one of the auxiliary classes.

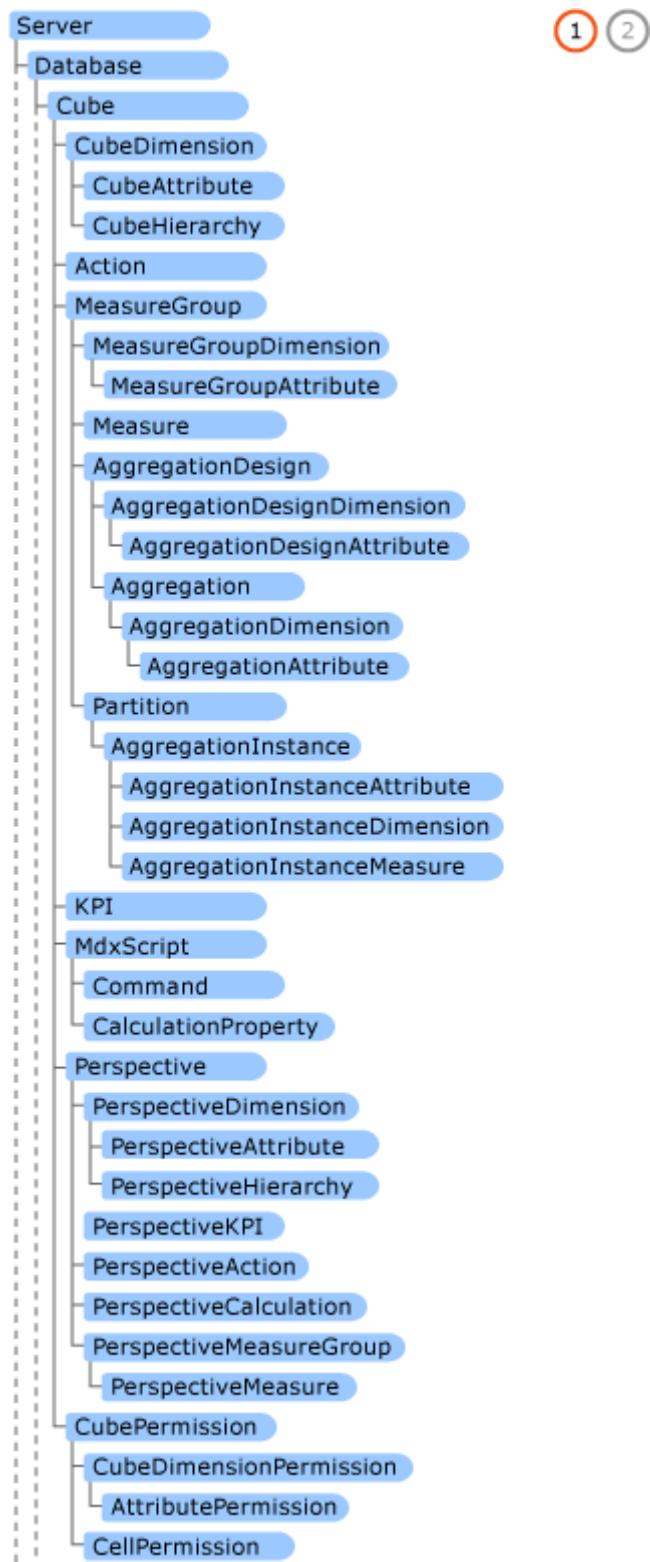

The following illustration is a high-level view of the AMO hierarchy that includes major classes. The illustration shows the placement of the classes among their containers and

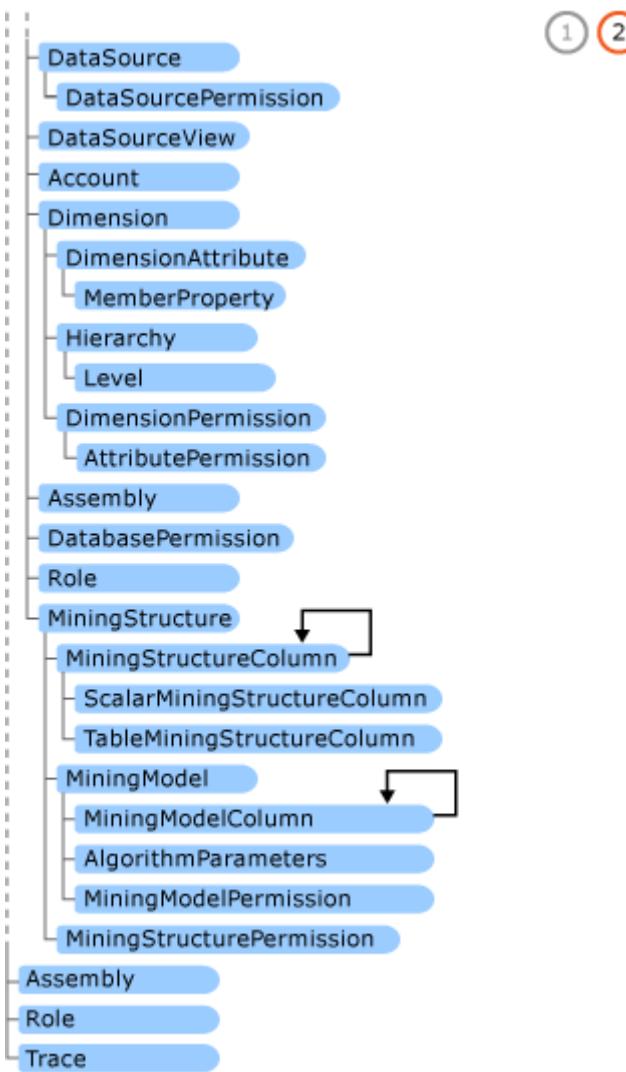

their peers. A [Dimension](#) belongs to a [Database](#) and a [Server](#), and can be created at the same time as a [DataSource](#) and [MiningStructure](#). Certain peer classes must be instantiated before you can use others. For example, you have to create an instance of [DataSource](#) before adding a new [Dimension](#) or [MiningStructure](#).

A *major object* is a class that represents a complete object as a whole entity and not as a part of another object. Major objects include [Server](#), [Cube](#), [Dimension](#), and [MiningStructure](#), because these are entities on their own. However, a [Level](#) is not a major object, because it is a constituent part of a [Dimension](#). Major objects can be created, deleted, modified, or processed independent of other objects. Minor objects are objects that can only be created as part of creating the parent major object. Minor objects are usually created upon a major object creation. Values for minor objects should be defined at creation time because there is no default creation for minor objects.

The following illustration shows the major objects that a [Server](#) object contains.

When programming with AMO, the association between classes and contained classes uses collection type attributes, for example [Server](#) and [Dimension](#). To work with one instance of a contained class, you first acquire a reference to a collection object that holds or can hold the contained class. Next, you find the specific object that you are looking for in the collection, and then you can obtain a reference to the object to start working with it.

## AMO classes

AMO is a library of classes designed to manage an instance of Analysis Services from a client application. The AMO library can be thought of as logically-related groups of objects that are used to accomplish a specific task. AMO classes can be categorized in the following way:

[Expand table](#)

Class Set	Purpose
<a href="#">AMO Fundamental</a>	Classes required in order to work with any other set of classes.

<b>Class Set</b>	<b>Purpose</b>
<a href="#">Classes</a>	
<a href="#">AMO OLAP Classes</a>	Classes that let you manage the OLAP objects.
<a href="#">AMO Data Mining Classes</a>	Classes that let you manage the data mining objects.
<a href="#">AMO Security Classes</a>	Classes that let you control access to other objects and maintain security.
<a href="#">AMO Other Classes and Methods</a>	Classes and methods that help OLAP or data mining administrators to complete their daily tasks.

## Using AMO

AMO is especially useful for automating repetitive tasks, for example creating new partitions in a measure group based on new data in the fact table, or re-training a mining model based on new data. These tasks that create new objects are usually performed on a monthly, weekly, or quarterly basis, and the new objects can easily be named, based in the new data, by the application.

## Analysis Services administrators

Administrators can use AMO to automate the processing of databases. For designing and deploying databases, use Visual Studio.

## Developers

Developers can use AMO to develop administrative interfaces for specified sets of users. These interfaces can restrict access to objects and limit users to certain tasks. For example, by using AMO you could create a backup application that enables a user to see all database objects, select any one of the databases, and backup it to any one of a specified set of devices.

Developers can also embed logic in their applications. For this, developers can create cubes, dimensions, mining structures, and mining models based on user input or other factors.

## OLAP advanced users

OLAP advanced users are usually data analysts or other experienced data users who have a strong programming background and who want to enhance their data analysis

with a closer usage of the data objects. For users who are required to work offline, AMO can be very useful to automate creating local cubes before going offline.

## Data mining advanced users

For data mining advanced users, AMO is most useful if you have large sets of models that periodically have to be re-trained.

## Automating administrative tasks with AMO

Most repetitive tasks are best designed, deployed, and maintained if they are developed by using Integration Services than if they are developed as an application in any language of your choice. However, for repetitive tasks that cannot be automated by using Integration Services, you can use AMO.

## Automatic object management

With AMO it's easy to create, update or delete objects (for example [Database](#), [Dimension](#), [Cube](#), mining [MiningStructure](#), and [MiningModel](#), or [Role](#)) based on user input or on new acquired data. AMO is ideal for setup applications that have to deploy a developed solution, from an independent software vendor to a final customer. The setup application can verify that an earlier version exists and can update the structure, remove no longer useful objects, and create new ones. If there is no earlier version then can create everything from scratch.

AMO can be powerful when creating new partitions based on new data, and can remove old partitions that had gone beyond the scope of the project. For example, for a finance analysis solution that works with the last 36 months of data, as soon as a new month of data is received, the 37th old month could be removed. To optimize performance, new aggregations can be designed based on usage and applied to the last 12 months.

## Automatic object processing

Object processing and updated availability can be achieved by using AMO to respond to certain events beyond the ordinary flow data and scheduled tasks that use Integration Services.

## Automatic security management

Security management can be automated to include new users to roles and permissions, or to remove other users as soon as their time has expired. New interfaces can be created to simplify security management for security administrators. This can be simpler than using Visual Studio.

## Automatic backup management

Automatic backup management can be done by using Integration Services tasks, or by creating specialized AMO applications that run automatically. By using AMO you can develop Backup interfaces for operators that help them in their daily jobs.

## Tasks AMO is not intended for querying data

AMO cannot be used to query the data. To query data, including cubes and mining models, use ADOMD.NET from a user application. For more information, see [Developing with ADOMD.NET](#).

# AMO Data Mining Classes

Article • 10/31/2023

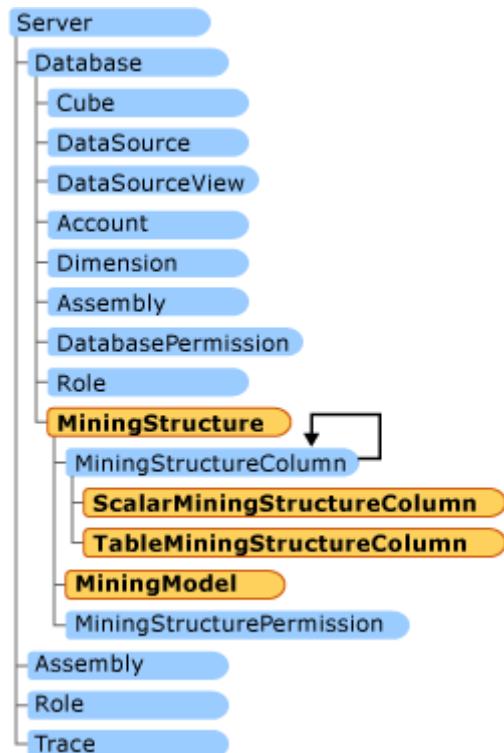

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Data mining classes help you create, modify, delete, and process data mining objects. Working with data mining objects includes creating data mining structures, creating data mining models, and processing the models.

For more information about how to set up the environment, and about [Server](#), [Database](#), [DataSource](#), and [DataSourceView](#) objects, see [AMO Fundamental Classes](#).

Defining objects in Analysis Management Objects (AMO) requires setting a number of properties on each object to set up the correct context. Complex objects, such as OLAP and data mining objects, require lengthy and detailed coding.

The following illustration shows the relationship of the classes that are explained in this topic.

## MiningStructure objects

A mining structure is the container for mining models. The structure defines all possible columns that the mining models may use. Each mining model defines its own columns from the set of defined columns in the structure.

A simple [MiningStructure](#) object is composed of: basic information, a data source view, one or more [ScalarMiningStructureColumn](#), zero or more [TableMiningStructureColumn](#), and a [MiningModelCollection](#).

Basic information includes the name and ID (internal identifier) of the [MiningStructure](#) object.

The [DataSourceView](#) object holds the underlying data model for the mining structure.

[ScalarMiningStructureColumn](#) are columns or attributes that have single values.

[TableMiningStructureColumn](#) are columns or attributes that have multiple values for each case.

[MiningModelCollection](#) contains all mining models built on the same data.

A [MiningStructure](#) object is created by adding it to the [MiningStructureCollection](#) of the database and updating the [MiningStructure](#) object to the server, by using the Update method.

To remove a [MiningStructure](#) object, it must be dropped by using the Drop method of the [MiningStructure](#) object. Removing a [MiningStructure](#) object from the collection does not affect the server.

The [MiningStructure](#) can be processed using its own process method, or it can be processed when a parent object processes itself with its own process method.

## Columns

Columns hold the data for the model and can be of different types depending on the usage: Key, Input, Predictable, or InputPredictable. Predictable columns are the target of building the mining model.

Single-value columns are known as [ScalarMiningStructureColumn](#) in AMO. Multiple-value columns are known as [TableMiningStructureColumn](#).

### ScalarMiningStructureColumn

A simple [ScalarMiningStructureColumn](#) object is composed of basic information, Type, Content, and data binding.

Basic information includes the name and ID (internal identifier) of the [ScalarMiningStructureColumn](#).

Type is the data type of the value: LONG, BOOLEAN, TEXT, DOUBLE, DATE.

Content tells the engine how the column can be modeled. Values can be: Discrete, Continuous, Discretized, Ordered, Cyclical, Probability, Variance, StdDev, ProbabilityVariance, ProbabilityStdDev, Support, Key.

Data binding is linking the data mining column with the underlying data model by using a data source view element.

A [ScalarMiningStructureColumn](#) is created by adding it to the parent [MiningStructureCollection](#), and updating the parent [MiningStructure](#) object to the server by using the Update method.

To remove a [ScalarMiningStructureColumn](#), it must be removed from the collection of the parent [MiningStructure](#), and the parent [MiningStructure](#) object must be updated to the server by using the Update method.

## TableMiningStructureColumn

A simple [TableMiningStructureColumn](#) object is composed of basic information and scalar columns.

Basic information includes the name and ID (internal identifier) of the [TableMiningStructureColumn](#).

Scalar columns are [ScalarMiningStructureColumn](#).

A [TableMiningStructureColumn](#) is created by adding it to the parent [MiningStructure](#) collection, and updating the parent [TableMiningStructureColumn](#) object to the server by using the Update method.

To remove a [ScalarMiningStructureColumn](#), it has to be removed from the collection of the parent [MiningStructure](#), and the parent [MiningStructure](#) object must be updated to the server by using the Update method.

## MiningModel Objects

A [MiningModel](#) is the object that allows you to choose which columns from the structure to use, an algorithm to use, and optionally specific parameters to tune the model. For example, you might want to define several mining models in the same mining structure that use the same algorithms, but to ignore some columns from the mining structure in one model, use them as inputs in another model, and use them as input and predict in a third model. This can be useful if in one mining model you want to treat a column as continuous, but in other model you want to treat the column as discretized.

A simple [MiningModel](#) object is composed of: basic information, algorithm definition, and columns.

Basic information includes the name and ID (internal identifier) of the mining model.

An algorithm definition refers to any one of the standard algorithms provided in Analysis Services, or any custom algorithms enabled on the server.

Columns are a collection of the columns that are used by the algorithm and their usage definition.

A [MiningModel](#) is created by adding it to the [MiningModelCollection](#) of the database and updating the [MiningModel](#) object to the server by using the Update method.

To remove a [MiningModel](#), it has to be dropped by using the Drop method of the [MiningModel](#). Removing a [MiningModel](#) from the collection does not affect the server.

After it is created, a [MiningModel](#) can be processed by using its own process method, or it can be processed when a parent object processes itself with its own process method.

# AMO Fundamental Classes

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Fundamental classes are the starting point for working with Analysis Management Objects (AMO). Through these classes you establish your environment for the rest of the objects that will be used in your application. Fundamental classes include the following objects: [Server](#), [Database](#), [DataSource](#), and [DataSourceView](#).

The following illustration shows the relationship of the classes that are explained in this topic.

## Server objects

Additionally, you will have access to the following methods:

- Connection management: Connect, Disconnect, Reconnect, and GetConnectionState.
- Transaction management: BeginTransaction, CommitTransaction, and RollbackTransaction.
- Backup and Restore.
- DDL execution: Execute, CancelCommand, SendXmlaRequest, StartXmlaRequest.
- Metadata management: UpdateObjects and Validate.

To connect to a server, you need a standard connection string, as used in ADOMD.NET and OLEDB. For more information, see [ConnectionString](#). The name of the server can be specified as a connection string without having to use a connection string format.

For more information about methods and properties available, see [Server](#) in the [Microsoft.AnalysisServices](#).

## Database objects

To work with a [Database](#) object in your application, you must get an instance of the database from the parent server databases collection. To create a database, you add a [Database](#) object to a server databases collection and update the new instance to the server. To delete a database, you drop the [Database](#) object by using its own Drop method.

Databases can be backed up by using the BackUp method (from the [Database](#) object or from the [Server](#) object), but can only be restored from the [Server](#) object with the Restore method.

For more information about methods and properties available, see [Database](#) in the [Microsoft.AnalysisServices](#).

## DataSource and DataSourceView Objects

Data sources are managed by using the [DataSourceCollection](#) from the database class. An instance of [DataSource](#) can be created by using the Add method from a [DataSourceCollection](#) object. An instance of [DataSource](#) can be deleted by using the Remove method from a [DataSourceCollection](#) object.

[DataSourceView](#) objects are managed from the [DataSourceViewCollection](#) object in the database class.

For more information about methods and properties available, see [DataSource](#) and [DataSourceView](#) in the [Microsoft.AnalysisServices](#).

# AMO OLAP classes

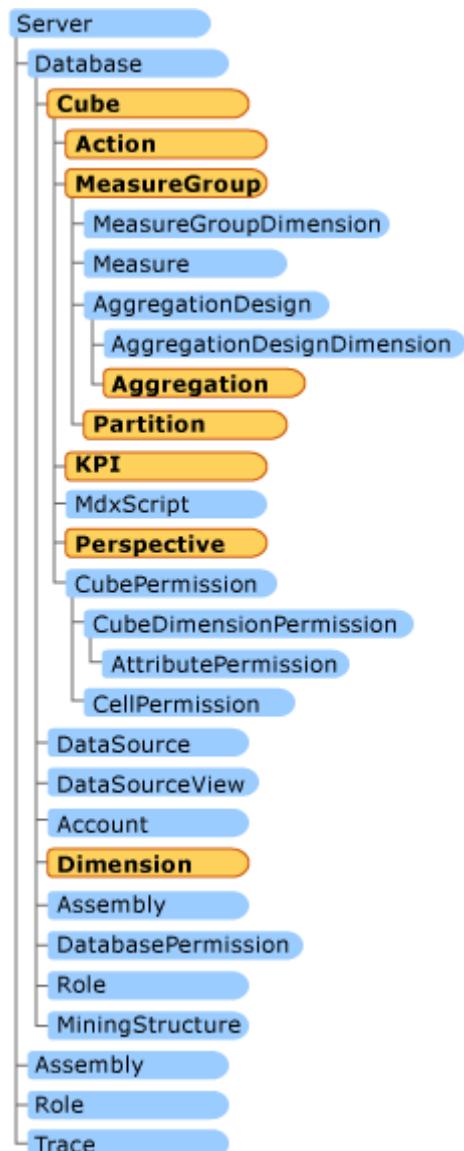

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Analysis Management Objects (AMO) OLAP classes help you create, modify, delete, and process cubes, dimensions, and related objects such as Key Performance Indicators (KPIs), actions, and proactive caching.

For more information about setting up the AMO programming environment, how to establish a connection with a server, accessing a database or defining data sources and data source views, see [AMO fundamental classes](#).

The following illustration shows the relationship of the classes that are explained in this topic.

# Basic classes

## Dimension objects

A dimension is created by adding it to the dimensions collection of the parent database, and by updating the [Dimension](#) object to the server by using the Update method.

To remove a dimension, it has to be dropped by using the Drop method of the [Dimension](#). Removing a [Dimension](#) from the dimensions collection of the database by using the Remove method does not delete it on the server, just in the AMO object model.

A [Dimension](#) object can be processed after it has been created. The [Dimension](#) can be processed using its own process method, or it can be processed with the parent object's process method when the parent object is processed.

For more information about methods and properties available, see [Dimension](#) in the [Microsoft.AnalysisServices](#).

## Cube objects

A cube is created by adding it to the cubes collection of the database, then updating the [Cube](#) object to the server by using the Update method. The Update method of the cube can include the parameter UpdateOptions.ExpandFull, which ensures that all objects in the cube that were modified will be updated to the server in this update action.

To remove a cube, it has to be dropped by using the Drop method of the [Cube](#). Removing a cube from the collection does not affect the server.

A [Cube](#) object can be processed after it has been created. The [Cube](#) can be processed using its own process method, or it can be processed when a parent object processes itself with its own Process method.

For more information about methods and properties available, see [Cube](#) in the [Microsoft.AnalysisServices](#).

## MeasureGroup objects

A measure group is created by adding it to the measure group collection of the cube, then updating the [MeasureGroup](#) object to the server by using its own Update method. A [MeasureGroup](#) object is removed using its own Drop method.

A [MeasureGroup](#) object can be processed after it has been created. The [MeasureGroup](#) can be processed by using its own Process method, or it can be processed when a parent object processes itself with its own Process method.

For more information about methods and properties available, see [MeasureGroup](#) in the [Microsoft.AnalysisServices](#).

## Partition objects

A [Partition](#) object is created by adding it to the partitions collection of the parent measure group, then updating the [Partition](#) object on the server by using the Update method. A [Partition](#) object is removed by using the Drop method.

For more information about methods and properties available, see [Partition](#) in the [Microsoft.AnalysisServices](#).

## AggregationDesign objects

Aggregation designs are constructed using the AggregationDesign method from an [AggregationDesign](#) object.

For more information about methods and properties available, see [AggregationDesign](#) in the [Microsoft.AnalysisServices](#).

## Aggregation objects

An [Aggregation](#) object is created by adding it to the aggregation designs collection of the parent measure group, then updating the parent measure group object on the server by using the Update method. An aggregation is removed from the [AggregationCollection](#) by using the Remove method or the RemoveAt method.

For more information about methods and properties available, see [Aggregation](#) in the [Microsoft.AnalysisServices](#).

## Advanced classes

Advanced classes provide OLAP functionality beyond building and browsing a cube. The following are some of the advanced classes and the benefits they provide:

- Action classes are used to create an active response when browsing certain areas of the cube.

- Key Performance Indicators (KPIs) enable comparison analysis between values of data.
- Perspectives provide selected views of a single cube, so that users can focus on what is important to them.
- Translations allow the cube to be customized to the user locale.
- Proactive caching classes can provide a balance between the enhanced performance of MOLAP storage and the immediacy of ROLAP storage, and provide scheduled partition processing.

AMO is used to set the definitions for this enhanced behavior, but the actual experience is defined by the browsing client that implements all of these enhancements.

## Action objects

An [Action](#) object is created by adding it to the actions collection of the cube, then updating the [Cube](#) object to the server by using the Update method. The update method of the cube can include the parameter `UpdateOptions.ExpandFull`, which ensures that all objects in the cube that were modified will be updated to the server with this update action.

To remove an [Action](#) object, it must be removed from the collection and the parent cube must be updated.

A cube must be updated and processed before the action can be used from the client.

For more information about methods and properties available, see [Action](#) in [Microsoft.AnalysisServices](#).

## Kpi objects

A [Kpi](#) object is created by adding it to the KPI collection of the cube, then updating the [Cube](#) object to the server by using the Update method. The Update method of the cube can include the parameter `UpdateOptions.ExpandFull`, which ensures that all objects in the cube that were modified will be updated to the server with this update action.

To remove a [Kpi](#) object, it must be removed from the collection, then and the parent cube must be updated.

A cube must be updated and processed before the KPI can be used.

For more information about methods and properties available, see [Kpi](#) in the [Microsoft.AnalysisServices](#).

## Perspective objects

A [Perspective](#) object is created by adding it to the perspective collection of the cube, then updating the [Cube](#) object to the server by using the Update method. The Update method of the cube can include the parameter `UpdateOptions.ExpandFull`, which ensures that all objects in the cube that were modified will be updated to the server with this update action.

To remove a [Perspective](#) object, it must be removed from the collection, then the parent cube must be updated.

A cube has to be updated and processed before the perspective can be used.

For more information about methods and properties available, see [Perspective](#) in the [Microsoft.AnalysisServices](#).

## Translation objects

A [Translation](#) object is created by adding it to the translation collection of the desired object, then updating the closest major parent object to the server by using the Update method. The Update method of the closest parent object can include the parameter `UpdateOptions.ExpandFull`, which ensures that all children objects that were modified will be updated to the server with this update action.

To remove a [Translation](#) object, it must be removed from the collection, then the closest parent object must be updated.

For more information about methods and properties available, see [Translation](#) in the [Microsoft.AnalysisServices](#).

## ProactiveCaching objects

A [ProactiveCaching](#) object is created by adding it to the proactive caching object collection of the dimension or partition, then updating the dimension or partition object to the server by using the Update method.

To remove a [ProactiveCaching](#) object, it must be removed from the collection, then the parent object must be updated.

A dimension or partition must be updated and processed before proactive caching is enabled and ready to be used.

For more information about methods and properties available, see [ProactiveCaching](#) in the [Microsoft.AnalysisServices](#).

# AMO other classes and methods

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

This section contains common classes that are not specific to OLAP or data mining, and that are helpful when administering or managing objects in Analysis Services. These classes cover features such as stored procedures, tracing, exceptions, and backup and restore.

The following illustration shows the relationship of the classes that are explained in this topic.

## Assembly objects

An [Assembly](#) object is created by adding it to the assemblies collection of the server, and then updating the [Assembly](#) object to the server, by using the Update method.

To remove an [Assembly](#) object, it has to be dropped by using the Drop method of the [Assembly](#) object. Removing an [Assembly](#) object from the assemblies collection of the database does not drop the assembly, it only prevents you from seeing it in your application until the next time that you run your application.

For more information about methods and properties available, see [Assembly](#) in [Microsoft.AnalysisServices](#).

**Important**

COM assemblies might pose a security risk. Due to this risk and other considerations, COM assemblies are no longer supported.

## Backup and restore methods

Backup and Restore are methods that can be used to create copies of a database and recover the database by using the copy. The Backup method belongs to the [Database](#) object, and the Restore method belongs to the [Server](#) object.

Only server and database administrators are permitted to perform a backup of a database. Only server administrators can restore a database onto a different server than it was backed up from. Database administrators can restore a database by overwriting the existing database only if they own the database that is to be overwritten. After a restore, the database administrator may lose access to the restored database if the database is restored with its original security definitions.

Database backup files must have .abf extensions.

### Backup method

To backup a database, use the Backup method of the database object with the name of the backup file as a parameter.

#### Default values

AllowOverwrite=**false**

BackupRemotePartitions=**false**

Security=**CopyAll**

ApplyCompression=**true**

### Restore method

To restore a database to a server, use the Restore method of the server with the backup file as a parameter.

#### Default values

AllowOverwrite=**false**

**DataSourceType=Remote**

**Security=CopyAll**

## Restrictions

1. A local partition cannot be restored as a remote partition.
2. A remote partition cannot be restored as a local partition, but a remote partition can be restored on a different server than it was backed up from.

## Common parameters and properties for Backup and Restore methods

- **File** is the name of the file to backup (UNC name) into/from.
- **Location** specifies server-specific backup information, such as **BackupFile**. This allows you to specify a separate backup file for a remote database.
- **DatasourceID** specifies the ID of the subordinate database in a remote server.
- **ConnectionString** allows you to adjust the remote datasource in case the remote server has changed. DatasourceID must always be specified when **ConnectionString** is present.
- **Folder** allows remapping of the folders for partitions on the local hard drive.
- **Original** is the original folder for local partitions.
- **New** is the new location for local partitions that used to reside in the corresponding 'Original' old folder.
- **Password**, if non-blank, specifies that the server will encrypt the backup file.

## Trace objects

Trace is a framework used for monitoring, replaying, and managing an instance of Analysis Services. A client application, like SQL Profiler, subscribes to a trace and the server sends back trace events as specified in the trace definition.

Each event is described by an event class. The event class describes the type of event generated. Within an event class, event subclasses describe a finer level of categorization. Each event is described by a number of columns. The columns that describe a trace event are consistent for all events and conform to the SQL trace

structure. Information recorded in each column may differ depending on the event class; that is, a predefined set of columns is defined for each trace, but the meaning of the column may differ depending on the event class. For example, the TextData column is used to record the original ASSL for all statement events.

A trace definition can include one or more event classes to be traced concurrently. For each event class, one or more data columns can be added to the trace definition, but not all trace columns must be used. The database administrator can decide which of the available columns to include in a trace. Further, event classes can be selectively traced based on filter criteria on any column in the trace.

Traces can be started and deleted. Multiple traces can be run at any one time. Trace events can be captured live or directed to a file for later analysis or replay. SQL Profiler is the tool used to analyze and replay trace events. Multiple connections are allowed to receive events from the same trace.

Traces can be divided in two groups: server traces and session traces. Server traces will inform of all events in the server; session traces will inform only events in the current session.

Traces, from the traces collection of the server, are defined the following way:

1. Create a [Trace](#) object and populate its basic data, including trace ID, name, log file name, append|overwrite, and others.
2. Add Events to be monitored to the Events collection of the trace object. For each event, data columns are added.
3. Set Filters to exclude unnecessary rows of data by adding them to the filters collection.
4. Start the trace; creating the trace does not start collecting data.
5. Stop the trace.
6. Review the trace file with SQL Profiler.

Traces, from the session object, are obtained in the following manner:

1. Define functions to handle the trace events generated in your application by SessionTrace. Possible events are OnEvent and Stopped.
2. Add your defined functions to the event handler.
3. Start the session trace.

4. Do your process and let your function handlers capture the events.

5. Stop the session trace.

6. Continue with your application.

## CaptureLog class and CaptureXML attribute

All actions to be executed by AMO are sent to the server as XMLA messages. AMO provides the means to capture all these messages without the SOAP headers. For more information, see [Introducing AMO Classes](#). CaptureLog is the mechanism in AMO for scripting out objects and operations; objects and operations will be scripted in XMLA.

To start capturing the XML, the CaptureXML server object property needs to be set to **true**. Then all actions that are to be sent to the server will start being captured in the CaptureLog class, without the actions being sent to the server. CaptureLog is considered a class because it has a method, **Clear**, which is used to clear the capture log.

To read the log, you get the strings collection and start iterating over the strings. Also, you can concatenate all logs into a string by using the server object method **ConcatenateCaptureLog**. **ConcatenateCaptureLog** requires has three parameters, two of which are required. The required parameters are *transactional*, of Boolean type, and *parallel*, of Boolean type. If *transactional* is set to **true**, it indicates that the XML batch file will be created as a single transaction instead of each command being treated as a separated transaction. If *parallel* is set to **true**, it indicates that all commands in the batch file will be recorded for concurrent execution instead of sequentially as they were recorded.

## AMOException exception class

You can use AMOException exception class to easily catch exceptions in your application that are thrown by AMO.

AMO will throw exceptions at different problems found. The following table lists the kind of exceptions that are handled by AMO. Exceptions are derived from the [AmoException](#) class.

[ ] Expand table

Exception	Origin	Description
<a href="#">AmoException</a>	Base class	Application receives this exception when a required parent object is missing, or when a

Exception	Origin	Description
		requested item is not found in a collection.
OutOfSyncException	Derived from AMOException	Application receives this exception when AMO is out of synchronization with the engine and the engine returns an object reference that AMO does not know about.
OperationException	Derived from AMOException	This is an important exception that is frequently received by applications. This exception contains the details of an error coming from the server, probably because of a faulty AMO operation like Update or Process or Drop.
ResponseFormatException	Derived from AMOException	This exception occurs when the engine returns a message in a format that AMO does not understand.
ConnectionException	Derived from AMOException	This exception occurs when a connection cannot be established (with Server.Connect) or when the connection is lost while AMO is communicating with the engine (for example, during an Update or Process or Drop).

# AMO Security classes

Article • 10/31/2023

Applies to: ✓ SQL Server Analysis Services ✓ Azure Analysis Services ✖  
Fabric/Power BI Premium

The following illustration shows the relationship of the classes that are explained in this topic:

## Role and RoleMember Objects

A [Role](#) object is created by adding it to the roles collection of the database, and updating the [Role](#) object to the server by using the Update method. A [Role](#) object has to be updated before it can be used.

To remove a [Role](#) object, it has to be dropped by using the Drop method of the [Role](#) object. The Remove method, from the roles collection, only prevents you from seeing the role in your application, but it does not remove the role from the server. A [Role](#) object cannot be dropped if there are any permissions associated with it.

A [RoleMember](#) object is created by adding a user to the members collection of the role and updating the [Role](#) object to the server by using the Update method. Only Server Administrators or Database Administrators are permitted to create roles. A [Role](#) object has to be updated to the server before any of its members is allowed to use any the objects to which the user has been granted permission.

To remove a [RoleMember](#) object, it has to be removed from the collection by using the Remove method of the collection, and then updating the role by using the Update method.

For more information about methods and properties available for these objects, see [Role](#) and [RoleMember](#) in the [Microsoft.AnalysisServices](#).

## Permission objects

A [Permission](#) object is created by adding it to the permissions collection of the object and updating the [Permission](#) object to the server by using the Update method.

To remove a [Permission](#) object, it has to be dropped by using the Drop method of the object. The remove method, from the permissions collection, only prevents you from seeing the permission in your application, but it does not remove the [Permission](#) object from the server. A role cannot be deleted if there is any permission associated with it.

For more information about methods and properties available, see [Permission](#) in [Microsoft.AnalysisServices](#).

# Programming administrative tasks with AMO

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Analysis Management Objects (AMO) is a programming library used from client applications to manage Analysis Services. The AMO library can be thought of as logically related groups of objects that are used to accomplish a specific task. In this section, you will learn to how to program using the AMO objects.

This section includes the following topics:

Expand table

Chapter	Contents
Programming AMO Fundamental Objects	Describes how to program the Server, Database, DataSource, and DataSourceView objects. Also included here is AMOException.
Programming AMO OLAP Basic Objects	Describes how to program the Dimension, Cube, MeasureGroup, Partition, and Aggregation objects.
Programming AMO OLAP Advanced Objects	Describes how to program the Action, KPI, Perspective, ProactiveCaching, and Translation objects.
Programming AMO Data Mining Objects	Describes how to program the MiningStructure and MiningModel objects.
Programming AMO Security Objects	Describes how to program the Roles, Members, and Permissions objects.
Programming AMO Complementary Classes and Methods	Describes how to program the Assembly object, Backup and Restore methods, Trace class, and also the CaptureLog class and CaptureXML attribute.

# Programming AMO Data Mining objects

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services   
Fabric/Power BI Premium

Programming data mining objects by using AMO is simple and straightforward. The first step is to create the data structure model to support the mining project. Then you create the data mining model that supports the mining algorithm you want to use in order to predict or to find the unseen relationships underlying your data. With your mining project created (including structure and algorithms), you can then process the mining models to obtain the trained models that you will use later when querying and predicting from the client application.

One thing to remember is that AMO is not for querying; AMO is for managing and administering your mining structures and models. To query your data, use [Developing with ADOMD.NET](#).

## MiningStructure objects

A mining structure is the definition of the data structure that is used to create all mining models. A mining structure contains a binding to a data source view that is defined in the database, and contains definitions for all columns participating in the mining models. A mining structure can have more than one mining model.

Creating a [MiningStructure](#) object requires the following steps:

1. Create the [MiningStructure](#) object and populate the basic attributes. Basic attributes include object name, object ID (internal identification), and data source binding.
2. Create columns for the model. Columns can be either scalar or table definitions.

Each column needs a name and internal ID, a type, a content definition, and a binding.

3. Update the [MiningStructure](#) object to the server, by using the Update method of the object.

Mining structures can be processed, and when they are processed, the children mining models are processed or retrained.

The following sample code creates a mining structure to forecast sales in a time series. Before running the sample code, make sure that the database *db*, passed as parameter for `CreateSalesForecastingMiningStructure`, contains in `db.DataSourceViews[0]` a reference to the view *dbo.vTimeSeries* in the Adventure Works Data Warehouse sample database.

C#

```
public static MiningStructure CreateSalesForecastingMiningStructure(Database db)
{
 MiningStructure ms = db.MiningStructures.FindByName("Forecasting Sales Structure");
 if (ms != null)
 ms.Drop();
 ms = db.MiningStructures.Add("Forecasting Sales Structure", "Forecasting Sales Structure");
 ms.Source = new DataSourceViewBinding(db.DataSourceViews[0].ID);

 ScalarMiningStructureColumn amount = ms.Columns.Add("Amount", "Amount");
 amount.Type = MiningStructureColumnTypes.Double;
 amount.Content = MiningStructureColumnContents.Continuous;
 amount.KeyColumns.Add("vTimeSeries", "Amount", OleDbType.Currency);

 ScalarMiningStructureColumn modelRegion = ms.Columns.Add("Model Region", "Model Region");
 modelRegion.IsKey = true;
 modelRegion.Type = MiningStructureColumnTypes.Text;
 modelRegion.Content = MiningStructureColumnContents.Key;
 modelRegion.KeyColumns.Add("vTimeSeries", "ModelRegion", OleDbType.WChar, 56);

 ScalarMiningStructureColumn qty = ms.Columns.Add("Quantity", "Quantity");
 qty.Type = MiningStructureColumnTypes.Long;
 qty.Content = MiningStructureColumnContents.Continuous;
 qty.KeyColumns.Add("vTimeSeries", "Quantity", OleDbType.Integer);

 ScalarMiningStructureColumn timeIndex = ms.Columns.Add("TimeIndex", "TimeIndex");
 timeIndex.IsKey = true;
 timeIndex.Type = MiningStructureColumnTypes.Long;
 timeIndex.Content = MiningStructureColumnContents.KeyTime;
 timeIndex.KeyColumns.Add("vTimeSeries", "TimeIndex", OleDbType.Integer);

 ms.Update();
 return ms;
}
```

## MiningModel objects

A mining model is a repository for all columns and column definitions that will be used in a mining algorithm.

Creating a [MiningModel](#) object requires the following steps:

1. Create the [MiningModel](#) object and populate the basic attributes.

Basic attributes include object name, object ID (internal identification), and mining algorithm specification.

2. Add the columns of the mining model. One of the columns must be defined as the case key.
3. Update the [MiningModel](#) object to the server, by using the Update method of the object.

[MiningModel](#) objects can be processed independently of other models in the parent [MiningStructure](#).

The following sample code creates a Microsoft Time Series forecasting model based on the "Forecasting Sales Structure" mining structure:

C#

```
public static MiningModel CreateSalesForecastingMiningModel(MiningStructure ms)
{
 if (ms.MiningModels.ContainsName("Sales Forecasting Model"))
 {
 ms.MiningModels["Sales Forecasting Model"].Drop();
 }
 MiningModel mm = ms.CreateMiningModel(true, "Sales Forecasting Model");
 mm.Algorithm = MiningModelAlgorithms.MicrosoftTimeSeries;
 mm.AlgorithmParameters.Add("PERIODICITY_HINT", "{12}");

 MiningModelColumn amount = new MiningModelColumn();
 amount.SourceColumnID = "Amount";
 amount.Usage = MiningModelColumnUsages.Predict;

 MiningModelColumn modelRegion = new MiningModelColumn();
 modelRegion.SourceColumnID = "Model Region";
 modelRegion.Usage = MiningModelColumnUsages.Key;

 MiningModelColumn qty = new MiningModelColumn();
 qty.SourceColumnID = "Quantity";
 qty.Usage = MiningModelColumnUsages.Predict;

 MiningModelColumn ti = new MiningModelColumn();
 ti.SourceColumnID = "TimeIndex";
 ti.Usage = MiningModelColumnUsages.Key;
```

```
 mm.Update();
 mm.Process(ProcessType.ProcessFull);
 return mm;
 }
```

# Programming AMO fundamental objects

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Fundamental objects are generally simple and straightforward objects. These objects are usually created and instantiated, then when they are no longer needed, the user disconnects from them. Fundamental classes include the following objects: [Server](#), [Database](#), [DataSource](#), and [DataSourceView](#). The only complex object in AMO fundamental objects is [DataSourceView](#), which requires detail to build the abstract model that represents the data source view.

[Server](#) and [Database](#) objects are usually required to use the contained objects as OLAP objects or data mining objects.

## Server objects

To use a [Server](#) object requires the following steps: connecting to the server, verifying whether the [Server](#) object is connected to the server, and if so, disconnecting the [Server](#) from the server.

### Connecting to the Server object

Connecting to the server consists of having the right connection string.

The following code sample returns a [Server](#) object if the connection is successful, or returns `null` if an error occurs. Errors during the connection process are handled in a try/catch construct. AMO errors are caught by using the [AmoException](#) exception class. In this example, the error is shown to the user on a message box.

C#

```
static Server ServerConnect(String strConnectionString)
{
 string methodCaption = "ServerConnect method";
 Server svr = new Server();
 try
 {
 svr.Connect(strConnectionString);
 }
```

```

#region ErrorHandling
catch (AmoException e)
{
 MessageBox.Show("AMO exception " + e.ToString());
 svr = null;
}
catch (Exception e)
{
 MessageBox.Show("General exception " + e.ToString());
 svr = null;
}
#endregion

return svr;
}

```

The structure of the connection string is:

"Data source=<server name>".

For a more information about connection string, see [ConnectionString](#).

## Validating the connection

Before programming the [Server](#) objects, you should verify that you are still connected to the server. The following code sample shows you how to do it. The sample assumes that `svr` is a [Server](#) object that exists in your code.

C#

```

if ((svr != null) && (svr.Connected))
{
 // Do what it is needed if connection is good
}

```

## Disconnecting from the server

As soon as you are finished, you can disconnect from the server by using the [Disconnect](#) method. The following code sample shows you how to do it. The sample assumes that `svr` is a [Server](#) object that exists in your code.

C#

```

if ((svr != null) && (svr.Connected))
{

```

```
 svr.Disconnect()
}
```

## AmoException exception objects

AMO will throw exceptions at different problems found. For a detailed explanation of exceptions, see [AMO Other Classes and Methods](#). The following sample code shows the correct way to capture exceptions in AMO:

C#

```
try
{
 //... some AMO code in here
}

catch (OutOfSynchException e)
{
 // error handling code for OutOfSynchException
}

catch (OperationException e)
{
 // error handling code for OperationException
}

catch (ResponseFormatException e)
{
 // error handling code for ResponseFormatException
}

catch (ConnectionException e)
{
 // error handling code for ConnectionException
}

catch (AmoException e)
{
 //... here is the place where you end if it is an AMO exception, but none
 // of the previous exceptions
 // if you start with AmoException in the first catch you will never see
 // any one of the previous exceptions
}
```

## Database objects

Working with a [Database](#) object is very simple and straightforward. You get an existing database from the database collection of the [Server](#) object.

## Creating, dropping, and finding a database

The following code sample shows how to create a database by using a database name. Before creating the database, query the [DatabaseCollection](#) of the server to see whether the database exists. If the database exists, the database is dropped and afterward created; if the database does not exist then it is created. If the database is to be dropped, then the database is first acquired from the databases collection.

C#

```
static Database CreateDatabase(Server svr, String DatabaseName)
{
 Database db = null;
 if ((svr != null) && (svr.Connected))
 {
 // Drop the database if it already exists
 db = svr.Databases.FindByName(DatabaseName);
 if (db != null)
 {
 db.Drop();
 }

 // Create the database
 db = svr.Databases.Add(DatabaseName);
 db.Update();
 }

 return db;
}
```

To determine whether a database exists in the database collection, the [FindByName](#) method is used. If the database exists, then the method returns the found database object, if not it returns a null object.

As soon as the [Database](#) object is added to the databases collection, the server has to be updated by using its [Update](#) method. Failing to update the server will cause the [Database](#) object not to be created in the server.

## Processing a database

Processing a database, with all the children objects, is very simple because the [Database](#) object includes a [Process](#) method.

The Process method can include parameters, but they are not required. If no parameters are specified, then all children objects will be processed with their **ProcessDefault** option. For more information about processing options, see [Database](#).

1. The following sample code process a database by its default value.

```
C#
```

```
static Database ProcessDatabase(Database db, ProcessType pt)
{
 db.Process(pt);
 return db;
}
```

## DataSource objects

A [DataSource](#) object is the link between the server and the database where the data resides. The schema that represents the underlying model for is defined by the [DataSourceView](#) object. A [DataSource](#) object can be seen as a connection string to the database where the data resides.

The following sample code shows how to create a [DataSource](#) object. The sample verifies that the server still exists, the [Server](#) object is connected, and the database exists. If the [DataSource](#) object exists, then it is dropped are re-created. The [DataSource](#) object is created having the same name and internal ID. In this sample, no checking is performed on the connection string to verify it.

```
C#
```

```
static string CreateDataSource(Database db, string strDataSourceName, string
strConnectionString)
{
 Server svr = db.Parent;
 DataSource ds = db.DataSources.FindByName(strDataSourceName);
 if (ds != null)
 ds.Drop();
 // Create the data source
 ds = db.DataSources.Add(strDataSourceName, strDataSourceName);
 ds.ConnectionString = strConnectionString;

 // Send the data source definition to the server.
 ds.Update();

 return ds.Name;
}
```

# DataSourceView objects

[DataSourceView](#) object is responsible for holding the schema model. For the [DataSourceView](#) object to hold the schema, the schema must first be constructed. Schemas are constructed over [DataSet](#) objects, from the [System.Data](#) namespace.

The following sample code will create part of the schema that is included in the Analysis Services sample project based on AdventureWorks. The sample creates schema definitions for tables, computed columns, relations, and composite relations. Schemas are persisted data sets.

The sample code does the following:

1. Create a [DataSourceView](#) object.

Verify first if the [DataSource](#) object exists; if `true`, then drop the [DataSource](#) and create it. If the [DataSource](#) does not exist, create it.

2. Open a connection to the database using [DataSource](#) connection string.

3. Create the schema.

The schema consists of the following:

- A table definition, `AddTable()` method.
- An optional set of calculated columns, `AddComputedColumn()` method.
- An optional set of relations, `AddRelation`.
- An optional set of composite relations, `AddCompositeRelations`.

4. Update the server.

## ① Note

The following sample code is trimmed for readability purposes; the complete code is included at the end of this topic.

## ① Note

The following methods are part of the sample code: `AddTable`, `AddComputedColumn`, `AddRelation`, and `AddCompositeRelation`.

## (!) Note

The clause '`WHERE 1=0`' is to avoid the query from returning rows to the `DataSet` object.

C#

```
static DataSourceView CreateDataSourceView(Database db, string
strDataSourceName)
{
 // Create the data source view
 DataSourceView dsv =
db.DataSourceViews.FindByName(strDataSourceName);
 if (dsv != null)
 dsv.Drop();
 dsv = db.DataSourceViews.Add(strDataSourceName);
 dsv.DataSourceID = strDataSourceName;
 dsv.Schema = new DataSet();
 dsv.Schema.Locale = CultureInfo.CurrentCulture;

 // Open a connection to the data source
 OleDbConnection connection
 = new OleDbConnection(dsv.DataSource.ConnectionString);
 connection.Open();

 #region Create tables

 // Add the DimTime table
 AddTable(dsv, connection, "DimTime");
 AddComputedColumn(dsv, connection, "DimTime", "SimpleDate",
"DATENAME(mm, FullDateAlternateKey) + ' ' + DATENAME(dd,
FullDateAlternateKey) + ',' + ' ' + DATENAME(yy, FullDateAlternateKey)");

 // Add the DimProductCategory table
 AddTable(dsv, connection, "DimProductCategory");

 // Add the DimProductSubcategory table
 AddTable(dsv, connection, "DimProductSubcategory");
 AddRelation(dsv, "DimProductSubcategory", "ProductCategoryKey",
"DimProductCategory", "ProductCategoryKey");

 // Add the FactInternetSales table
 AddTable(dsv, connection, "FactInternetSales");
"DimTime", "TimeKey");
 AddRelation(dsv, "FactInternetSales", "ShipDateKey", "DimTime",
"TimeKey");
 AddRelation(dsv, "FactInternetSales", "DueDateKey", "DimTime",
"TimeKey");

 // Add the FactInternetSalesReason table
 AddTable(dsv, connection, "FactInternetSalesReason");
 AddCompositeRelation(dsv, "FactInternetSalesReason",
```

```

 "FactInternetSales", "SalesOrderNumber", "SalesOrderLineNumber");
 dsv.Update();

 #endregion

 // Send the data source view definition to the server
 dsv.Update();

 return dsv;
}

static void AddTable(DataSourceView dsv, OleDbConnection connection,
String tableName)
{
 string strSelectText = "SELECT * FROM [dbo].[{" + tableName + "]
WHERE 1=0";
 OleDbDataAdapter adapter = new OleDbDataAdapter(strSelectText,
connection);
 DataTable[] dataTables = adapter.FillSchema(dsv.Schema,
SchemaType.Mapped, tableName);
 DataTable dataTable = dataTables[0];

 dataTable.ExtendedProperties.Add("TableType", "Table");
 dataTable.ExtendedProperties.Add("DbSchemaName", "dbo");
 dataTable.ExtendedProperties.Add("DbTableName", tableName);
 dataTable.ExtendedProperties.Add("FriendlyName", tableName);

 dataTable = null;
 dataTables = null;
 adapter = null;
}

static void AddComputedColumn(DataSourceView dsv, OleDbConnection
connection, String tableName, String computedColumnName, String expression)
{
 DataSet tmpDataSet = new DataSet();
 tmpDataSet.Locale = CultureInfo.CurrentCulture;
 OleDbDataAdapter adapter = new OleDbDataAdapter("SELECT (
 + expression + ") AS [{" + computedColumnName + "}] FROM
[dbo].[{"
 + tableName + "} WHERE 1=0", connection);
 DataTable[] dataTables = adapter.FillSchema(tmpDataSet,
SchemaType.Mapped, tableName);
 DataTable dataTable = dataTables[0];
 DataColumn dataColumn = dataTable.Columns[computedColumnName];

 dataTable.Constraints.Clear();
 dataTable.Columns.Remove(dataColumn);

 dataColumn.ExtendedProperties.Add("DbColumnName",
computedColumnName);
 dataColumn.ExtendedProperties.Add("ComputedColumnExpression",
expression);
 dataColumn.ExtendedProperties.Add("IsLogical", "True");
}

```

```

dsv.Schema.Tables[tableName].Columns.Add(dataColumn);

dataColumn = null;
dataTable = null;
dataTables = null;
adapter = null;
tmpDataSet = null;
}

static void AddRelation(DataSourceView dsv, String fkTableName,
String fkColumnName, String pkTableName, String pkColumnName)
{
 DataColumn fkColumn
 = dsv.Schema.Tables[fkTableName].Columns[fkColumnName];
 DataColumn pkColumn
 = dsv.Schema.Tables[pkTableName].Columns[pkColumnName];
 dsv.Schema.Relations.Add("FK_" + fkTableName + "_"
 + fkColumnName, pkColumn, fkColumn, true);
}

static void AddCompositeRelation(DataSourceView dsv, String
fkTableName, String pkTableName, String columnName1, String columnName2)
{
 DataColumn[] fkColumns = new DataColumn[2];
 fkColumns[0] =
dsv.Schema.Tables[fkTableName].Columns[columnName1];
 fkColumns[1] =
dsv.Schema.Tables[fkTableName].Columns[columnName2];

 DataColumn[] pkColumns = new DataColumn[2];
 pkColumns[0] =
dsv.Schema.Tables[pkTableName].Columns[columnName1];
 pkColumns[1] =
dsv.Schema.Tables[pkTableName].Columns[columnName2];

 dsv.Schema.Relations.Add("FK_" + fkTableName + "_" + columnName1
 + "_" + columnName2, pkColumns, fkColumns, true);
}

```

In the sample code, the `AddTable` and `AddComputedColumn` methods use the `FillSchema` method of the `DataAdapter` object to add a `DataTable` to a `DataSet` and to configure the schema to match that in the data source. The extended properties add required info to configure the schema.

In the sample code, the `AddRelation` and `AddCompositeRelation` methods add the relation columns, depending on the existing schema and the existing columns on the model. Columns must be part of the tables defined in the schema for these methods to work.

The following is the complete code sample:

C#

```
static DataSourceView CreateDataSourceView(Database db, string
strDataSourceName)
{
 // Create the data source view
 DataSourceView dsv = db.DataSourceViews.FindByName(strDataSourceName);
 if (dsv != null)
 dsv.Drop();
 dsv = db.DataSourceViews.Add(strDataSourceName);
 dsv.DataSourceID = strDataSourceName;
 dsv.Schema = new DataSet();
 dsv.Schema.Locale = CultureInfo.CurrentCulture;

 // Open a connection to the data source
 OleDbConnection connection
 = new OleDbConnection(dsv.DataSource.ConnectionString);
 connection.Open();

#region Create tables

 // Add the DimTime table
 AddTable(dsv, connection, "DimTime");
 AddComputedColumn(dsv, connection, "DimTime", "SimpleDate",
"DATENAME(mm, FullDateAlternateKey) + ' ' + DATENAME(dd,
FullDateAlternateKey) + ',' + ' ' + DATENAME(yy, FullDateAlternateKey)");
 AddComputedColumn(dsv, connection, "DimTime", "CalendarYearDesc", "'CY'
+ ' ' + CalendarYear");
 AddComputedColumn(dsv, connection, "DimTime", "CalendarSemesterDesc",
"CASE WHEN CalendarSemester = 1 THEN 'H1'+' '+ 'CY' +' '+ CONVERT(CHAR (4),
CalendarYear) ELSE 'H2'+' '+ 'CY' +' '+ CONVERT(CHAR (4), CalendarYear)
END");
 AddComputedColumn(dsv, connection, "DimTime", "CalendarQuarterDesc",
"'Q' + CONVERT(CHAR (1), CalendarQuarter) +' '+ 'CY' +' '+ CONVERT(CHAR (4),
CalendarYear)");
 AddComputedColumn(dsv, connection, "DimTime", "MonthName",
"EnglishMonthName+' '+ CONVERT(CHAR (4), CalendarYear)");
 AddComputedColumn(dsv, connection, "DimTime", "FiscalYearDesc", "'FY' +
' ' + FiscalYear");
 AddComputedColumn(dsv, connection, "DimTime", "FiscalSemesterDesc",
"CASE WHEN FiscalSemester = 1 THEN 'H1'+' '+ 'FY' +' '+ CONVERT(CHAR (4),
FiscalYear) ELSE 'H2'+' '+ 'FY' +' '+ CONVERT(CHAR (4), FiscalYear) END");
 AddComputedColumn(dsv, connection, "DimTime", "FiscalQuarterDesc", "'Q'
+ CONVERT(CHAR (1), FiscalQuarter) +' '+ 'FY' +' '+ CONVERT(CHAR (4),
FiscalYear)");
 AddComputedColumn(dsv, connection, "DimTime", "FiscalMonthNumberOfYear",
"CASE WHEN MonthNumberOfYear = '1' THEN CONVERT(int,'7') WHEN
MonthNumberOfYear = '2' THEN CONVERT(int,'8') WHEN MonthNumberOfYear = '3'
THEN CONVERT(int,'9') WHEN MonthNumberOfYear = '4' THEN CONVERT(int,'10')

# Programming AMO OLAP advanced objects

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services   
Fabric/Power BI Premium

This topic explains the Analysis Management Objects (AMO) programming details of OLAP advanced objects.

## Action objects

Action classes are used to create an active response when browsing certain areas of the cube. Action objects can be defined by using AMO, but are used from the client application that browses the data. Actions can be of different types and they have to be created according to their type. Actions can be:

- Drillthrough actions, which return the set of rows that represents the underlying data of the selected cells of the cube where the action occurs.
- Reporting actions, which return a report from that is associated with the selected section of the cube where the action occurs.
- Standard actions, which return the action element (URL, HTML, DataSet, RowSet, and other elements) that is associated with the selected section of the cube where the action occurs.

Creating an action object requires the following steps:

1. Create the derived action object and populate basic attributes.

The following are the basic attributes: type of action, target type or section of the cube, target or specific area of the cube where the action is available, caption and where the caption is an MDX expression.

2. Populate the specific attributes of the action type.

Attributes are different for the three types of actions, see the code sample that follows for parameters.

3. Add the action to the cubes collection and update the cube. The action is not an updatable object.

Testing the action requires a different program application. You can test your action in Visual Studio.

The following sample code replicates three different actions from the Adventure Works Analysis Services Project sample. You can differentiate the actions because the ones that you introduce by using the following sample, start with "My".

C#

```
static public void CreateActions(Cube cube)
{
 #region Adding a drillthrough action
 // Verify That action exists and drop it
 if (cube.Actions.ContainsName("My Reseller Details"))
 cube.Actions.Remove("My Drillthrough Action",true);

 //Create a Drillthrough action
 DrillThroughAction dtaction = new DrillThroughAction("My Reseller
Details", "My Drillthrough Action");

 //Define the Action
 dtaction.Type = ActionType.DrillThrough;
 dtaction.TargetType = ActionTargetType.Cells;
 dtaction.Target = "MeasureGroupMeasures(\"Reseller Sales\")";
 dtaction.Caption = "My Drillthrough...";
 dtaction.CaptionIsMdx = false;

 #region create drillthrough action specifics
 //Adding Drillthrough columns
 //Adding Measure columns to the drillthrough
 MeasureGroup mg = cube.MeasureGroups.FindByName("Reseller Sales");
 MeasureBinding mb1 = new MeasureBinding();
 mb1.MeasureID = mg.Measures.FindByName("Reseller Sales Amount").ID;
 dtaction.Columns.Add(mb1);

 MeasureBinding mb2 = new MeasureBinding();
 mb2.MeasureID = mg.Measures.FindByName("Reseller Order Quantity").ID;
 dtaction.Columns.Add(mb2);

 MeasureBinding mb3 = new MeasureBinding();
 mb3.MeasureID = mg.Measures.FindByName("Reseller Unit Price").ID;
 dtaction.Columns.Add(mb3);

 //Adding Dimension Columns to the drillthrough
 CubeAttributeBinding cb1 = new CubeAttributeBinding();
 cb1.CubeID = cube.ID;
 cb1.CubeDimensionID = cube.Dimensions.FindByName("Reseller").ID;
 cb1.AttributeID = "Reseller Name";
 cb1.Type = AttributeBindingType.All;
 dtaction.Columns.Add(cb1);

 CubeAttributeBinding cb2 = new CubeAttributeBinding();
 cb2.CubeID = cube.ID;
```

```

cb2.CubeDimensionID = cube.Dimensions.FindByName("Product").ID;
cb2.AttributeID = "Product Name";
cb2.Type = AttributeBindingType.All;
dtaction.Columns.Add(cb2);
#endregion

//Add the defined action to the cube
cube.Actions.Add(dtaction);
#endregion

#region Adding a Standard action
// Verify That action exists and drop it
if (cube.Actions.ContainsName("My City Map"))
 cube.Actions.Remove("My Action", true);

//Create a Drillthrough action
StandardAction stdaction = new StandardAction("My City Map", "My
Action");

//Define the Action
stdaction.Type = ActionType.Url;
stdaction.TargetType = ActionTargetType.AttributeMembers;
stdaction.Target = "[Geography].[City]";
stdaction.Caption = "\"My View Map for \" + [Geography].
[City].CurrentMember.Member_Caption + "...\"";
stdaction.CaptionIsMdx = true;

#region create standard action specifics
stdaction.Expression = "\"http://maps.msn.com/home.aspx?plce1=" +
 "[Geography].[City].CurrentMember.Name + "," + " +
 "[Geography].[State-Province].CurrentMember.Name + ",\\" + " +
 "[Geography].[Country].CurrentMember.Name + " +

 "Then \"3\" " +
 "When [Geography].[Country].CurrentMember Is " +
 "[Geography].[Country].&[Canada] " +
 "Or [Geography].[Country].CurrentMember Is " +
 "[Geography].[Country].&[United States] " +
 "Then \"0\" " +
 "Else \"1\" " +
 "End ";
#endregion

//Add the defined action to the cube
cube.Actions.Add(stdaction);

#endregion

#region Adding a Reporting action
// Verify That action exists and drop it
if (cube.Actions.ContainsName("My Sales Reason Comparisons"))
 cube.Actions.Remove("My Report Action", true);

```

```

//Create a Report action
ReportAction rsaction = new ReportAction("My Sales Reason Comparisons",
"My Report Action");

//Define the Action
rsaction.Type = ActionType.Report;
rsaction.TargetType = ActionTargetType.AttributeMembers;
rsaction.Target = "[Product].[Category]";
rsaction.Caption = "\"My Sales Reason Comparisons for \" + [Product].
[Category].CurrentMember.Member_Caption + \"...\"";
rsaction.CaptionIsMdx = true;

#region create Report action specifics
rsaction.ReportServer = "MyRSSamplesServer";
rsaction.Path = "ReportServer?/AdventureWorks Sample Reports/Sales
Reason Comparisons";
rsaction.ReportParameters.Add("ProductCategory", "UrlEscapeFragment(
[Product].[Category].CurrentMember.UniqueName)");
rsaction.ReportFormatParameters.Add("rs:Command", "Render");
rsaction.ReportFormatParameters.Add("rs:Renderer", "HTML5");
#endregion

//Add the defined action to the cube
cube.Actions.Add(rsaction);

#endregion
}

```

## KPI objects

A key performance indicator (KPI) is a collection of calculations that are associated with a measure group in a cube and are used to evaluate business success. [Kpi](#) objects can be defined by AMO, but are used from the client application that browses the data.

Creating a [Kpi](#) object requires the following steps:

1. Create the [Kpi](#) object and populate the basic attributes.

The following is a list of basic attributes: Description, Display Folder, Associated Measure Group, and Value. Display Folder tells the client application where the KPI should be located for the end-user to find it. The Associated Measure Group indicates the measure group where all MDX calculations should be referred. Value shows the actual value of the performance indicator as an MDX expression.

2. Define KPI Indicators: Goal, Status, and Trend.

Indicators are MDX expressions that should evaluate between -1 to 1, but is the browsing application which defines the range of values for the indicators.

3. When you browse KPIs, values less than -1 are treated as -1, and values larger than 1 are treated as 1.

4. Define graphic images.

Graphic images are string values, used as reference in the client application to identify the correct set of images to display. The graphic image string also defines the behavior of the display function. Usually the range is split in an odd number of states, from bad to good, and to each state an image, from the set, is assigned.

If you use Visual Studio to browse your KPIs, then depending on names, the indicator range is split into either three states or five states. In addition, there are names where the range is inverted, that is -1 is 'Good' and 1 is 'Bad'. In Visual Studio, three states within the range are as follows:

- Bad = -1 to -0.5
- OK = -0.4999 to -0.4999
- Good = 0.50 to 1

In Visual Studio, five states within the range are as follows:

- Bad = -1 to -0.75
- Risk = -0.7499 to -0.25
- OK = -0.2499 to 0.2499
- Raising = 0.25 to 0.7499
- Good = 0.75 to 1

The following table lists the Usage, Name, and the number of states associated with the image.

[+] [Expand table](#)

Image usage	Image Name	Number of States
Status	Shapes	3
Status	Traffic Light	3
Status	Road Signs	3
Status	Gauge	3

Image usage	Image Name	Number of States
Status	Reversed Gauge	5
Status	Thermometer	3
Status	Cylinder	3
Status	Faces	3
Status	Variance arrow	3
Trend	Standard Arrow	3
Trend	Status Arrow	3
Trend	Reversed status arrow	5
Trend	Faces	3

1. Add the KPI to the cube collection and update the cube, because the KPI is not an updatable object.

Testing the KPI requires a different program application. You can test your KPI in Visual Studio.

The following sample code creates a KPI in the "Financial Perspective/Grow Revenue" folder for the Adventure Works cube that is included in the Adventure Works Analysis Services Project sample.

C#

```
static public void CreateKPIs(Cube cube)
{
 Kpi kpi = cube.Kpis.Add("My Internet Revenue", "My Internet Revenue");
 kpi.Description = "(My) Revenue achieved through direct sales via
 Interner";
 kpi.DisplayFolder = "\\Financial Perspective\\Grow Revenue";
 kpi.AssociatedMeasureGroupID = "Internet Sales";
 kpi.Value = "[Measures].[Internet Sales Amount]";
 #region Goal
 kpi.Goal = "Case" +
 " When IsEmpty" +
 "(" +
 " ParallelPeriod" +
 "(" +
 " [Date].[Fiscal Time].[Fiscal Year], " +
 " 1, " +
 " [Date].[Fiscal Time].CurrentMember" +
 ")" +
 ")" +
 ")"
}
```

```

 " Then [Measures].[Internet Sales Amount]" +
 " Else 1.10 *" +
 " (" +
 " [Measures].[Internet Sales Amount]," +
 " ParallelPeriod" +
 " (" +
 " [Date].[Fiscal Time].[Fiscal Year]," +
 " 1," +
 " [Date].[Fiscal Time].CurrentMember" +
 ")" +
 ") " +
 " End";
#endregion
#region Status
kpi.Status = "Case" +
 " When KpiValue(\"Internet Revenue\") / KpiGoal (
\"Internet Revenue\") >= .95 " +
 " Then 1 " +
 " When KpiValue(\"Internet Revenue\") / KpiGoal (
\"Internet Revenue\") < .95 " +
 " And " +
 " KpiValue(\"Internet Revenue\") / KpiGoal (
\"Internet Revenue\") >= .85 " +
 " Then 0 " +
 " Else -1 " +
"End";
#endregion
#region Trend
kpi.Trend = "Case " +
 " When VBA!Abs " +
 " (" +
 " KpiValue(\"Internet Revenue\") - " +
 " (" +
 " KpiValue (\"Internet Revenue\"), " +
 " ParallelPeriod " +
 " (" +
 " [Date].[Fiscal Time].[Fiscal Year], " +
 " 1, " +
 " [Date].[Fiscal Time].CurrentMember " +
 ")" +
 ") / " +
 " (" +
 " KpiValue (\"Internet Revenue\"), " +
 " ParallelPeriod " +
 " (" +
 " [Date].[Fiscal Time].[Fiscal Year], " +
 " 1, " +
 " [Date].[Fiscal Time].CurrentMember " +
 ")" +
 ") " +
 ") <=.02 " +
 " Then 0 " +
 " When KpiValue(\"Internet Revenue\") - " +
 " (" +
 " KpiValue (\"Internet Revenue\"), " +

```

```

 " ParallelPeriod " +
 " (" +
 " [Date].[Fiscal Time].[Fiscal Year], " +
 " 1, " +
 " [Date].[Fiscal Time].CurrentMember " +
 ") " +
 ") / " +
 " (" +
 " KpiValue (\"Internet Revenue\"), " +
 " ParallelPeriod " +
 " (" +
 " [Date].[Fiscal Time].[Fiscal Year], " +
 " 1, " +
 " [Date].[Fiscal Time].CurrentMember " +
 ") " +
 ") >.02 " +
 " Then 1 " +
 " Else -1 " +
 "End";
#endregion
kpi.TrendGraphic = "Standard Arrow";
kpi.StatusGraphic = "Cylinder";
}.

```

## Perspective objects

[Perspective](#) objects can be defined by AMO, but are used from the client application that browses the data.

Creating a [Perspective](#) object requires the following steps:

1. Create the [Perspective](#) object and populate the basic attributes.

The following is a list of basic attributes: Name, Default Measure, Description, and annotations.

2. Add all objects from the parent cube that should be seen by end user.

Add cube dimensions (attributes and hierarchies), measure groups (measure and measure group), actions, KPIs, and calculations.

3. Add the perspective to the cube collection and update the cube, because perspective is not an updatable object.

Testing the perspective requires a different program application.

The following code sample creates a perspective named "Direct Sales" for the supplied cube.

C#

```
static public void CreatePerspectives(Cube cube)
{
 Perspective perspective = cube.Perspectives.Add("Direct Sales", "Direct Sales");
 CubeDimension dim1 = cube.Dimensions.GetByName("Date");
 PerspectiveDimension pdim1 =
perspective.Dimensions.Add(dim1.DimensionID);
 pdim1.Attributes.Add("Date");
 pdim1.Attributes.Add("Calendar Year");
 pdim1.Attributes.Add("Fiscal Year");
 pdim1.Attributes.Add("Calendar Quarter");
 pdim1.Attributes.Add("Fiscal Quarter");
 pdim1.Attributes.Add("Calendar Month Number");
 pdim1.Attributes.Add("Fiscal Month Number");
 pdim1.Hierarchies.Add("Calendar Time");
 pdim1.Hierarchies.Add("Fiscal Time");

 CubeDimension dim2 = cube.Dimensions.GetByName("Product");
 PerspectiveDimension pdim2 =
perspective.Dimensions.Add(dim2.DimensionID);
 pdim2.Attributes.Add("Product Name");
 pdim2.Attributes.Add("Product Line");
 pdim2.Attributes.Add("Model Name");
 pdim2.Attributes.Add("List Price");
 pdim2.Attributes.Add("Size");
 pdim2.Attributes.Add("Weight");
 pdim2.Hierarchies.Add("Product Model Categories");
 pdim2.Hierarchies.Add("Product Categories");

 PerspectiveMeasureGroup pmg = perspective.MeasureGroups.Add("Internet Sales");
 pmg.Measures.Add("Internet Sales Amount");
 pmg.Measures.Add("Internet Order Quantity");
 pmg.Measures.Add("Internet Unit Price");

 pmg = perspective.MeasureGroups.Add("Reseller Sales");
 pmg.Measures.Add("Reseler Sales Amount");
 pmg.Measures.Add("Reseller Order Quantity");
 pmg.Measures.Add("Reseller Unit Price");

 PerspectiveAction pact = perspective.Actions.Add("Drillthrough Action");

 PerspectiveKpi pkpi = perspective.Kpis.Add("Internet Revenue");
 Cube.Update();
}
```

## ProactiveCaching objects

ProactiveCaching objects can be defined by AMO.

Creating a [ProactiveCaching](#) object requires the following steps:

1. Create the [ProactiveCaching](#) object.

There are no basic attributes to define.

2. Add cache specifications.

[\[+\] Expand table](#)

Specification	Description
AggregationStorage	The type of storage for aggregations.  Applies to partition only. On dimension it must be <b>Regular</b> .
SilenceInterval	Minimum amount of time the cache exists before the MOLAP imaging starts.
Latency	The amount of time between the earliest notification and the moment when the MOLAP images are destroyed.
SilenceOverrideInterval	The time after an initial notification after which the MOLAP imaging kicks in unconditionally.
ForceRebuildInterval	The time (starting after a fresh MOLAP image is dropped) after which MOLAP imaging starts unconditionally (no notifications).
OnlineMode	When the MOLAP image is available.  Can be either <b>Immediate</b> or <b>OnCacheComplete</b> .

1. Add the [ProactiveCaching](#) object to the parent collection. You will need to update the parent, because [ProactiveCaching](#) is not an updatable object.

The following code sample creates a [ProactiveCaching](#) object in all partitions from the Internet Sales measure group in the Adventure Works cube in a specified database.

C#

```
static public void SetProactiveCachingSettings(Database db)
{
 ProactiveCaching pc;
 if (db.Cubes.ContainsName("Adventure Works") &&
 db.Cubes.FindByName("Adventure Works").MeasureGroups.ContainsName("Internet
Sales"))
 {
 ProactiveCachingTablesBinding pctb;
 TableNotification tn;
```

```

 MeasureGroup mg = db.Cubes.FindByName("Adventure
Works").MeasureGroups.FindByName("Internet Sales");
 foreach(Partition part in mg.Partitions)
 {
 pc = new ProactiveCaching();
 pc.AggregationStorage =
ProactiveCachingAggregationStorage.MolapOnly;
 pc.SilenceInterval = TimeSpan.FromSeconds(10);
 pc.Latency = TimeSpan.FromSeconds(-1);
 pc.SilenceOverrideInterval = TimeSpan.FromMinutes(10);
 pc.ForceRebuildInterval = TimeSpan.FromSeconds(-1);
 pc.Enabled = true;
 pc.OnlineMode = ProactiveCachingOnlineMode.OnCacheComplete;
 pctb = new ProactiveCachingTablesBinding();
 pctb.NotificationTechnique = NotificationTechnique.Server;
 tn = new TableNotification("[FactInternetSales]", "dbo");
 pctb.TableNotifications.Add(tn);
 pc.Source = pctb;

 part.ProactiveCaching = pc;
 part.Update();
 }
 }
}

```

## Translation objects

Translation objects can be defined by AMO, but are used from the client application that browses the data. Translation objects are simple objects to code. Translations for object captions are provided by pairs of Locale Identifier and Translated Caption. For any caption, multiple translations can be enabled. Translations can be provided for most objects, such as dimensions, attributes, hierarchies, cubes, measure groups, measures, and others.

The following code sample provides a Spanish translation for the name of the attribute Product Name.

C#

```

static public void CreateTranslations(Database db)
{
 //Spanish Tranlations for Product Category in Product Dimension
 Dimension dim = db.Dimensions["Product"];
 DimensionAttribute atr = dim.Attributes["Product Name"];
 Translation tran = atr.Translations.Add(3082);
 tran.Caption = "Nombre Producto";

 dim.Update(UpdateOptions.ExpandFull);
}

```

}

# Programming AMO OLAP basic objects

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Creating complex Analysis Services objects is simple and straightforward but requires attention to detail. This topic explains the programming details of OLAP basic objects. This topic contains the following sections:

## Dimension objects

To administer or process a dimension, you program the [Dimension](#) object.

### Creating, dropping, and finding a Dimension

Creating a [Dimension](#) object is accomplished in four steps:

1. Create the dimension object and populate basic attributes.

Basic attributes are Name, Dimension Type, Storage Mode, Data Source Binding, Attribute All Member Name, and other dimension attributes.

Before creating a dimension, you should verify that the dimension does not already exist. If the dimension exists, then the dimension is dropped and re-created.

2. Create the attributes that define the dimension.

Each attribute has to be added individually to the schema before using it (find `CreateDataItem` method at the end of the sample code), and then can be added to the attributes collection of the dimension.

Key and Name column must be defined in all attributes.

The primary key attribute of the dimension should be defined as `AttributeUsage.Key` to make clear that this attribute is the key access to the dimension.

3. Create the hierarchies that the user will access to navigate the dimension.

When you are creating hierarchies, the level order is defined by the order in which levels are created from top to bottom. The highest level is the first added to the

levels collection of the hierarchy.

4. Update the server by using the Update method of the current dimension.

The following sample code creates the Product dimension from the Adventure Works products table in the sample database.

C#

```
static void CreateProductDimension(Database db, string datasourceName)
{
 // Create the Product dimension
 Dimension dim = db.Dimensions.FindByName("Product");
 if (dim != null)
 dim.Drop();
 dim = db.Dimensions.Add("Product");
 dim.Type = DimensionType.Products;
 dim.UnknownMember = UnknownMemberBehavior.Hidden;
 dim.AttributeAllMemberName = "All Products";
 dim.Source = new DataSourceViewBinding(datasourceName);
 dim.StorageMode = DimensionStorageMode.Molap;

 #region Create attributes

 DimensionAttribute attr;

 attr = dim.Attributes.Add("Product Name");
 attr.Usage = AttributeUsage.Key;
 attr.Type = AttributeType.Product;
 attr.OrderBy = OrderBy.Name;
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
 "ProductKey"));
 attr.NameColumn = CreateDataItem(db.DataSourceViews[0], "DimProduct",
 "EnglishProductName");

 attr = dim.Attributes.Add("Product Line");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
 "ProductLine"));
 attr.NameColumn = CreateDataItem(db.DataSourceViews[0], "DimProduct",
 "ProductLineName");

 attr = dim.Attributes.Add("Model Name");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
 "modelName"));
 attr.AttributeRelationships.Add(new AttributeRelationship("Product
 Line"));
 attr.AttributeRelationships.Add(new
 AttributeRelationship("Subcategory"));

 attr = dim.Attributes.Add("Subcategory");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
 "DimProductSubcategory", "ProductSubcategoryKey"));
 attr.KeyColumns[0].NullProcessing = NullProcessing.UnknownMember;
```

```

 attr.NameColumn = CreateDataItem(db.DataSourceViews[0],
"DimProductSubcategory", "EnglishProductSubcategoryName");
 attr.AttributeRelationships.Add(new AttributeRelationship("Category"));

 attr = dim.Attributes.Add("Category");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"DimProductCategory", "ProductCategoryKey"));
 attr.NameColumn = CreateDataItem(db.DataSourceViews[0],
"DimProductCategory", "EnglishProductCategoryName");

 attr = dim.Attributes.Add("List Price");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
"ListPrice"));
 attr.AttributeHierarchyEnabled = false;

 attr = dim.Attributes.Add("Size");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
"Size"));
 attr.AttributeHierarchyEnabled = false;

 attr = dim.Attributes.Add("Weight");
 attr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0], "DimProduct",
"Weight"));
 attr.AttributeHierarchyEnabled = false;

#endregion

#region Create hierarchies

Hierarchy hier;

hier = dim.Hierarchies.Add("Product Model Categories");
hier.AllMemberName = "All Products";
hier.Levels.Add("Category").SourceAttributeID = "Category";
hier.Levels.Add("Subcategory").SourceAttributeID = "Subcategory";
hier.Levels.Add("Model Name").SourceAttributeID = "Model Name";

hier = dim.Hierarchies.Add("Product Categories");
hier.AllMemberName = "All Products";
hier.Levels.Add("Category").SourceAttributeID = "Category";
hier.Levels.Add("Subcategory").SourceAttributeID = "Subcategory";
hier.Levels.Add("Model Name").SourceAttributeID = "Product Name";

hier = dim.Hierarchies.Add("Product Model Lines");
hier.AllMemberName = "All Products";
hier.Levels.Add("Subcategory").SourceAttributeID = "Product Line";
hier.Levels.Add("Model Name").SourceAttributeID = "Model Name";

#endregion

dim.Update();
}

static DataItem CreateDataItem(DataSourceView dsv, string tableName, string
columnName)

```

```
{
 DataTable dataTable = ((DataSourceView)dsv).Schema.Tables[tableName];
 DataColumn dataColumn = dataTable.Columns[columnName];
 return new DataItem(tableName, columnName,
 OleDbTypeConverter.GetRestrictedOleDbType(dataColumn.DataType));
}
```

## Processing a dimension

Processing a dimension is as simple as using the `Process` method of the [Dimension](#) object.

Processing a dimension can affect all cubes that use the dimension.

The following code does an incremental update in all dimensions of a supplied database:

C#

```
static void UpdateAllDimensions(Database db)
{
 foreach (Dimension dim in db.Dimensions)
 dim.Process(ProcessType.ProcessUpdate);
}
```

## Cube objects

To administer or process a cube, you program the [Cube](#) object.

## Creating, dropping, and finding a cube

Managing cubes is similar to managing dimensions. Creating a [Cube](#) object is accomplished in four steps:

1. Create the cube object and populate basic attributes.

Basic attributes are Name, Storage Mode, Data Source Binding, Default Measure, and other cube attributes.

Before creating a cube you should verify that the cube does not exist. In the sample if the cube exists the cube is dropped and then re-created.

2. Add the dimensions of the cube.

Dimensions are added to the current cube dimensions collection from the database; dimensions in the cube are references to the database dimensions collection. Each dimension has to be mapped to the cube individually. In the sample dimensions are mapped providing: the database dimension Internal Identifier, a Name for the dimension in the cube and an Id for the named dimension in the cube.

In the sample code notice that "Date" dimension is added three times, every time is added by using a different cube dimension name: Date, Ship Date, Delivery Date. These dimensions are called "role playing" dimensions. The base dimension is the same (Date), but in the fact table the dimension is used in different "roles" (Order Date, Ship Date, Delivery Date) -see "Creating, dropping and finding a MeasureGroup" later in this document to understand how "role playing" dimensions are defined.

3. Create the Measure Groups that the user will access to browse the data of the cube.

Measure group creation will be explained in "Creating, dropping and finding a MeasureGroup" later in this document. The sample wraps measure group creation in different methods, one for each measure group.

4. Update the server by using the Update method of current cube.

The update method is used with the Update option ExpandFull to make sure that all objects are fully updated in the server.

The following code sample creates the parts of the Adventure Works cube. The code sample does not create all dimensions or measure groups that are included in the Adventure Works Analysis Services Project sample.

```
C#
```

```
static void CreateAdventureWorksCube(Database db, string datasourceName)
{
 // Create the Adventure Works cube
 Cube cube = db.Cubes.FindByName("Adventure Works");
 if (cube != null)
 cube.Drop();
 db.Cubes.Add("Adventure Works");
 cube.DefaultMeasure = "[Reseller Sales Amount]";
 cube.Source = new DataSourceViewBinding(datasourceName);
 cube.StorageMode = StorageMode.Molap;

 #region Create cube dimensions

 Dimension dim;
```

```

dim = db.Dimensions.GetByName("Date");
cube.Dimensions.Add(dim.ID, "Date", "Order Date Key - Dim Time");
cube.Dimensions.Add(dim.ID, "Ship Date",
 "Ship Date Key - Dim Time");
cube.Dimensions.Add(dim.ID, "Delivery Date",
 "Delivery Date Key - Dim Time");

dim = db.Dimensions.GetByName("Customer");
cube.Dimensions.Add(dim.ID);

dim = db.Dimensions.GetByName("Reseller");
cube.Dimensions.Add(dim.ID);
#endregion

#region Create measure groups

CreateSalesReasonsMeasureGroup(cube);
CreateInternetSalesMeasureGroup(cube);
CreateResellerSalesMeasureGroup(cube);
CreateCustomersMeasureGroup(cube);
CreateCurrencyRatesMeasureGroup(cube);

#endregion

cube.Update(UpdateOptions.ExpandFull);
}

```

## Processing a cube

Processing a cube is as simple as using the `Process` method of the `Cube` object. Processing a cube also processes all measure groups in the cube, and all partitions in the measure group. In a cube, partitions are the only objects that can be processed; for the purposes of processing, measure groups are only containers of partitions. The specified type of processing for the cube propagates to the partitions. Processing of cube and measure group internally is resolved to processing of dimensions and partitions.

The following code will do a full process on all cubes in a specified database:

C#

```

foreach (Cube cube in db.Cubes)
 cube.Process(ProcessType.ProcessFull);
}

```

## MeasureGroup objects

To administer or process a measure group, you program the [MeasureGroup](#) object.

## Creating, dropping, and finding a MeasureGroup

Managing measure groups is similar to managing dimensions and cubes. Creating a [MeasureGroup](#) object is accomplished in the following steps:

1. Create the measure group object and populate the basic attributes.

Basic attributes include Name, Storage Mode, Processing Mode, Default Measure, and other measure group attributes.

Before creating a measure group, verify that the measure group does not exist. In the sample code that follows, if the measure group exists, then the measure group is dropped and re-created.

2. Create the measures of the measure group. For each measure created, the following attributes are assigned: name, aggregation function, source column, format string. Other attributes can also be assigned. Note that in the sample code that follows, the `CreateDataItem` method adds the column to the schema.

3. Add the dimensions of the measure group.

4. Dimensions are added to the current measure group dimensions collection from the parent cube dimensions collection. As soon as the dimension is included in the measure group dimensions collection, a key column from the fact table can be mapped to the dimension so that the measure group can be browsed through the dimension.

In the sample code that follows, see the lines under "Mapping dimension and key column from fact table". The role playing dimensions are implemented by linking different surrogate keys to the same dimension under different names. For each one of the role playing dimensions (Date, Ship Date, Delivery Date), a different surrogate key is linked to it (`OrderDateKey`, `ShipDateKey`, `DueDateKey`). All keys are from the fact table `FactInternetSales`.

5. Add the designed partitions of the measure group.

The in the sample code that follows, partition creation is wrapped in one method.

6. Update the server by using the `Update` method of current measure group.

In the sample code that follows, all measure groups are updated when the cube is updated.

The following sample code will create the InternetSales measure group of the Adventure Works Analysis Services Project sample.

C#

```
static void CreateInternetSalesMeasureGroup(Cube cube)
{
 // Create the Internet Sales measure group
 Database db = cube.Parent;
 MeasureGroup mg = cube.MeasureGroups.FindByName("Internet Sales");
 if (mg != null)
 mg.Drop();
 mg = cube.MeasureGroups.Add("Internet Sales");
 mg.StorageMode = StorageMode.Molap;
 mg.ProcessingMode = ProcessingMode.LazyAggregations;
 mg.Type = MeasureGroupType.Sales;

 #region Create measures

 Measure meas;

 meas = mg.Measures.Add("Internet Sales Amount");
 meas.AggregateFunction = AggregationFunction.Sum;
 meas.FormatString = "Currency";
 meas.Source = CreateDataItem(db.DataSourceViews[0], "FactInternetSales",
 "SalesAmount");

 meas = mg.Measures.Add("Internet Order Quantity");
 meas.AggregateFunction = AggregationFunction.Sum;
 meas.FormatString = "#,#";
 meas.Source = CreateDataItem(db.DataSourceViews[0], "FactInternetSales",
 "OrderQuantity");

 meas = mg.Measures.Add("Internet Unit Price");
 meas.AggregateFunction = AggregationFunction.Sum;
 meas.FormatString = "Currency";
 meas.Visible = false;
 meas.Source = CreateDataItem(db.DataSourceViews[0], "FactInternetSales",
 "UnitPrice");

 meas = mg.Measures.Add("Internet Total Product Cost");
 meas.AggregateFunction = AggregationFunction.Sum;
 //meas.MeasureExpression = "[Internet Total Product Cost] * [Average
 Rate]";
 meas.FormatString = "Currency";
 meas.Source = CreateDataItem(db.DataSourceViews[0], "FactInternetSales",
 "TotalProductCost");

 meas = mg.Measures.Add("Internet Order Count");
 meas.AggregateFunction = AggregationFunction.Count;
 meas.FormatString = "#,#";
 meas.Source = CreateDataItem(db.DataSourceViews[0], "FactInternetSales",
 "ProductKey");
}
```

```

#endregion

#region Create measure group dimensions

CubeDimension cubeDim;
RegularMeasureGroupDimension regMgDim;
ManyToManyMeasureGroupDimension mmMgDim;
MeasureGroupAttribute mgAttr;

// Mapping dimension and key column from fact table
// > select dimension and add it to the measure group
cubeDim = cube.Dimensions.GetByName("Date");
regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
mg.Dimensions.Add(regMgDim);

// > add key column from dimension and map it with
// the surrogate key in the fact table
mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Date").ID);
// this is dimension key column
mgAttr.Type = MeasureGroupAttributeType.Granularity;
mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "OrderDateKey")); // this surrogate key in fact table

cubeDim = cube.Dimensions.GetByName("Ship Date");
regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
mg.Dimensions.Add(regMgDim);
mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Date").ID);
mgAttr.Type = MeasureGroupAttributeType.Granularity;
mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "ShipDateKey"));

cubeDim = cube.Dimensions.GetByName("Delivery Date");
regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
mg.Dimensions.Add(regMgDim);
mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Date").ID);
mgAttr.Type = MeasureGroupAttributeType.Granularity;
mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "DueDateKey"));

cubeDim = cube.Dimensions.GetByName("Customer");
regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
mg.Dimensions.Add(regMgDim);
mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Full
Name").ID);
mgAttr.Type = MeasureGroupAttributeType.Granularity;
mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "CustomerKey"));

cubeDim = cube.Dimensions.GetByName("Product");
regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
mg.Dimensions.Add(regMgDim);

```

```

 mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Product
Name").ID);
 mgAttr.Type = MeasureGroupAttributeType.Granularity;
 mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "ProductKey"));

 cubeDim = cube.Dimensions.GetByName("Source Currency");
 regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
 mg.Dimensions.Add(regMgDim);
 mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Currency").I
D);
 mgAttr.Type = MeasureGroupAttributeType.Granularity;
 mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "CurrencyKey"));

 cubeDim = cube.Dimensions.GetByName("Sales Reason");
 mmMgDim = new ManyToManyMeasureGroupDimension();
 mmMgDim.CubeDimensionID = cubeDim.ID;
 mmMgDim.MeasureGroupID = cube.MeasureGroups.GetByName("Sales
Reasons").ID;
 mg.Dimensions.Add(mmMgDim);

 cubeDim = cube.Dimensions.GetByName("Internet Sales Order Details");
 regMgDim = new RegularMeasureGroupDimension(cubeDim.ID);
 mg.Dimensions.Add(regMgDim);
 mgAttr =
regMgDim.Attributes.Add(cubeDim.Dimension.Attributes.GetByName("Sales Order
Key").ID);
 mgAttr.Type = MeasureGroupAttributeType.Granularity;
 mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "SalesOrderNumber"));
 mgAttr.KeyColumns.Add(CreateDataItem(db.DataSourceViews[0],
"FactInternetSales", "SalesOrderLineNumber"));

#endregion

#region Create partitions

CreateInternetSalesMeasureGroupPartitions(mg)

#endregion
}

```

## Processing a measure group

Processing a measure group is as simple as using the `Process` method of the `MeasureGroup` object. Processing a measure group will process all partitions that belong to the measure group. Processing a measure group internally is resolved to processing dimensions and partitions. See [Processing a Partition](#) in this document.

The following code will do a full process in all measure groups of a supplied cube.

C#

```
static void FullProcessAllMeasureGroups(Cube cube)
{
 foreach (MeasureGroup mg in cube.MeasureGroups)
 mg.Process(ProcessType.ProcessFull);
}
```

## Partition objects

To administer or process a partition, you program a [Partition](#) object.

### Creating, dropping, and finding a partition

Partitions are simple objects that can be created in two steps.

1. Create the partition object and populate the basic attributes.

Basic attributes are Name, Storage Mode, partition source, Slice, as well as other measure group attributes. Partition source defines the SQL select statement for current partition. Slice is an MDX expression specifying a tuple or a set that delimits a part of the dimensions from the parent measure group that are contained in the current partition. For MOLAP partitions, slicing is determined automatically every time that the partition is processed.

Before creating a partition, you should verify that the partition does not exist. In the sample code that follows, if the partition exists, it is dropped and then re-created.

2. Update the server by using the Update method of the current partition.

In the sample code that follows, all partitions are updated when the cube is updated.

The following code sample creates partitions for the 'InternetSales' measure group.

C#

```
static void CreateInternetSalesMeasureGroupPartitions(MeasureGroup mg)
{
 Partition part;
 part = mg.Partitions.FindByName("Internet_Sales_184");
 if (part != null)
```

```

 part.Drop();
 part = mg.Partitions.Add("Internet_Sales_184");
 part.StorageMode = StorageMode.Molap;
 part.Source = new QueryBinding(db.DataSources[0].ID, "SELECT * FROM
[dbo].[FactInternetSales] WHERE OrderDateKey <= '184'");
 part.Slice = "[Date].[Calendar Year].&[2001]";
 part.Annotations.Add("LastOrderDateKey", "184");

 part = mg.Partitions.FindByName("Internet_Sales_549");
 if (part != null)
 part.Drop();
 part = mg.Partitions.Add("Internet_Sales_549");
 part.StorageMode = StorageMode.Molap;
 part.Source = new QueryBinding(db.DataSources[0].ID, "SELECT * FROM
[dbo].[FactInternetSales] WHERE OrderDateKey > '184' AND OrderDateKey <=
'549'");
 part.Slice = "[Date].[Calendar Year].&[2002]";
 part.Annotations.Add("LastOrderDateKey", "549");

 part = mg.Partitions.FindByName("Internet_Sales_914");
 if (part != null)
 part.Drop();
 part = mg.Partitions.Add("Internet_Sales_914");
 part.StorageMode = StorageMode.Molap;
 part.Source = new QueryBinding(db.DataSources[0].ID, "SELECT * FROM
[dbo].[FactInternetSales] WHERE OrderDateKey > '549' AND OrderDateKey <=
'914'");
 part.Slice = "[Date].[Calendar Year].&[2003]";
 part.Annotations.Add("LastOrderDateKey", "914");
 }
}

```

## Processing a partition

Processing a partition is as simple as using the [Process](#) method of the [Partition](#) object.

The following code sample does a full process in all partitions of a specified measure group.

C#

```

static void FullProcessAllPartitions(MeasureGroup mg)
{
 foreach (Partition part in mg.Partitions)
 part.Process(ProcessType.ProcessFull);
}

```

## Merging partitions

Merging partitions means performing any operation that results in two or more partitions becoming one partition.

Merging partitions is a method of the [Partition](#) object. This command merges the data of one or more source partitions into a target partition and deletes the source partitions.

Partitions can be merged only if they meet all the following criteria:

- Partitions are in the same measure group.
- Partitions are stored in the same mode (MOLAP, HOLAP, and ROLAP).
- Partitions reside on the same server; remote partitions can be merged if on the same server.

Unlike previous versions, in Analysis Services, it is not necessary that all source partitions have identical aggregations design.

The resulting set of aggregations for the target partition is the same set of aggregations as of the state before running merge command.

The following code sample merges all partitions of a specified measure group. The partitions are merged into the first partition of the measure group.

C#

```
static void MergeAllPartitions(MeasureGroup mg)
{
 if (mg.Partitions.Count > 1)
 {
 Partition[] partArray = new Partition[mg.Partitions.Count - 1];
 for (int i = 1; i < mg.Partitions.Count; i++)
 partArray[i - 1] = mg.Partitions[i];
 mg.Partitions[0].Merge(partArray);
 //To have last changes in the server reflected in AMO
 mg.Refresh();
 }
}
```

## Aggregation objects

To design an aggregation and apply it to one or more partitions, you program [Aggregation](#) object.

## Creating and dropping aggregations

Aggregations can easily be created and assigned to measure groups or to partitions by using the `DesignAggregations` method from the [AggregationDesign](#) object. The [AggregationDesign](#) object is a separate object from partition, the [AggregationDesign](#) object is contained in the [MeasureGroup](#) object. Aggregations can be designed up to specified level of optimization (0 to 100) or up to specified level of storage (bytes). Multiple partitions can use the same aggregation design.

The following code sample creates aggregations for all partitions of a supplied measure group. Any existing aggregations in partitions are dropped.

C#

```
static public String DesignAggregationsOnPartitions(MeasureGroup mg, double optimizationWanted, double maxStorageBytes)
{
 double optimization = 0;
 double storage = 0;
 long aggCount = 0;
 bool finished = false;
 AggregationDesign ad = null;
 String aggDesignName;
 String AggregationsDesigned = "";
 aggDesignName = mg.AggregationPrefix + "_" + mg.Name;
 ad = mg.AggregationDesigns.Add();
 ad.Name = aggDesignName;
 ad.InitializeDesign();
 while ((!finished) && (optimization < optimizationWanted) && (storage < maxStorageBytes))
 {
 ad.DesignAggregations(out optimization, out storage, out aggCount,
 out finished);
 }
 ad.FinalizeDesign();
 foreach (Partition part in mg.Partitions)
 {
 part.AggregationDesignID = ad.ID;
 AggregationsDesigned += aggDesignName + " = " + aggCount.ToString()
 + " aggregations designed\r\n\tOptimization: " + optimization.ToString() +
 "/ " + optimizationWanted.ToString() + "\n\r\tStorage: " + storage.ToString() +
 "/ " + maxStorageBytes.ToString() + "]\n\r";
 }
 return AggregationsDesigned;
}
```

# Programming AMO security objects

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

In Analysis Services, programming security objects or running applications that use AMO security objects requires being a member of the Server Administrator group or the Database Administrator group. Server Administrator and Database Administrator.

In Analysis Services, user access to any object is obtained through the combination of Roles and Permissions assigned to that object. For more information, see [AMO Security Classes](#).

## Role and permission objects

Server roles contain one and only one role in the collection, the Administrators role. New roles cannot be added to the server roles collection. Membership in the Administrators role permits complete access to every object in the server.

[Role](#) objects are created at database level. Role maintenance requires only adding or removing members to or from the role, and adding or dropping roles to the [Database](#) object. A role cannot be dropped if there is any [Permission](#) object associated with the role. To drop a role, all [Permission](#) objects in the [Database](#) objects must be searched, and the [Role](#) removed from permissions, before the [Role](#) can be dropped from the [Database](#).

Permissions define the enabled actions on the object where the permission is supplied. Permissions can be supplied to the following objects: [Database](#), [DataSource](#), [Dimension](#), [Cube](#), [MiningStructure](#), and [MiningModel](#). Permission maintenance involves granting or revoking enabled access by the corresponding access property. For each enabled access, there is a property that can be set to the desired level of access. Access can be defined for the following operations: Process, ReadDefinition, Read, Write, and Administer. Administer access is only defined on the [Database](#) object. The database administrator security level is obtained when the role is granted with the Administer database permission.

The following sample creates four roles: Database Administrators, Processors, Writers, and Readers.

Database Administrators can administer the supplied database.

Processors can process all objects in a database and verify results. To verify results, read access to the database object must be explicitly enabled to the supplied cube, because read permission does not apply to children objects.

Writers can read and write to the supplied cube, and cell access is limited to the 'United States' in the customer dimension.

Readers can read on the supplied cube, and cell access is limited to the 'United States' in the customer dimension.

```
C#
```

```
static public void CreateRolesAndPermissions(Database db, Cube cube)
{
 Role role;
 DatabasePermission dbperm;
 CubePermission cubeperm;

 #region Create the Database Administrators role

 // Create the Database Administrators role.
 role = db.Roles.Add("Database Administrators");
 role.Members.Add(new RoleMember(""));
 role.Update();

 // Assign administrative permissions to this role.
 // Members of this role can perform any operation within the database.
 dbperm = db.DatabasePermissions.Add(role.ID);
 dbperm.Administer = true;
 dbperm.Update();

 #endregion

 #region Create the Processors role

 // Create the Processors role.
 role = db.Roles.Add("Processors");
 role.Members.Add(new RoleMember(""));
 role.Update();

 // Assign Read and Process permissions to this role.
 // Members of this role can process objects in the database and query them to verify results.
 // Process permission applies to all contained objects, i.e. all dimensions and cubes.
 // Read permission does not apply to contained objects, so we must assign the permission explicitly on the cubes.
 dbperm = db.DatabasePermissions.Add(role.ID);
 dbperm.Read = ReadAccess.Allowed;
 dbperm.Process = true;
 dbperm.Update();
}
```

```

 cubeperm = cube.CubePermissions.Add(role.ID);
 cubeperm.Read = ReadAccess.Allowed;
 cubeperm.Update();

#endregion

#region Create the Writers role

// Create the Writers role.
role = db.Roles.Add("Writers");
role.Members.Add(new RoleMember(""));
role.Update();

// Assign Read and Write permissions to this role.
// Members of this role can discover, query and writeback to the
Adventure Works cube.
// However cell access and writeback is restricted to the United States
(in the Customer dimension).
dbperm = db.DatabasePermissions.Add(role.ID);
dbperm.Read = ReadAccess.Allowed;
dbperm.Update();

cubeperm = cube.CubePermissions.Add(role.ID);
cubeperm.Read = ReadAccess.Allowed;
cubeperm.Write = WriteAccess.Allowed;
cubeperm.CellPermissions.Add(new
CellPermission(CellPermissionAccess.Read, "[Customer].[Country-
Region].CurrentMember is [Customer].[Country-Region].[Country-Region].&
[United States]"));
cubeperm.CellPermissions.Add(new
CellPermission(CellPermissionAccess.ReadWrite, "[Customer].[Country-
Region].CurrentMember is [Customer].[Country-Region].[Country-Region].&
[United States]"));
cubeperm.Update();

#endregion

#region Create the Readers role

// Create the Readers role.
role = db.Roles.Add("Readers");
role.Members.Add(new RoleMember(""));
role.Update();

// Assign Read permissions to this role.
// Members of this role can discover and query the Adventure Works cube.
// However the Customer dimension is restricted to the United States.
dbperm = db.DatabasePermissions.Add(role.ID);
dbperm.Read = ReadAccess.Allowed;
dbperm.Update();

cubeperm = cube.CubePermissions.Add(role.ID);
cubeperm.Read = ReadAccess.Allowed;
Dimension dim = db.Dimensions.GetByName("Customer");
DimensionAttribute attr = dim.Attributes.GetByName("Country-Region");

```

```
 CubeDimensionPermission cubedimperm =
cubeperm.DimensionPermissions.Add(dim.ID);
 cubedimperm.Read = ReadAccess.Allowed;
 AttributePermission attrperm =
cubedimperm.AttributePermissions.Add(attr.ID);
 attrperm.AllowedSet = "[Customer].[Country-Region].[Country-Region].&
[United States]}";
 cubeperm.Update();

#endregion
}
```

# Programming AMO complementary classes and methods

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

## Assembly class

Assemblies let users extend the functionality of Analysis Services by adding new stored procedures or Multidimensional Expressions (MDX) functions. For more information, see [AMO other classes and methods](#).

Adding and dropping assemblies is simple and can be performed online. You must be a database administrator to add an assembly to the database or a server administrator to add the assembly to the server object.

The following sample adds an assembly to the provided database and assigns the service account to run the assembly. If the assembly exists in the database, the assembly is dropped before trying to add it.

C#

```
static public void CreateStoredProcedures(Database db)
{
 ClrAssembly clrAssembly;

 // Verify That assembly exist in database and drop it
 if (db.Assemblies.ContainsName("StoredProcedures"))
 {
 clrAssembly = db.Assemblies.FindByName("StoredProcedures");
 clrAssembly.Drop();
 }

 // Create the CLR assembly
 clrAssembly = db.Assemblies.Add("StoredProcedures");
 clrAssembly.ImpersonationInfo = new ImpersonationInfo(
 ImpersonationMode.ImpersonateServiceAccount);
 clrAssembly.PermissionSet = PermissionSet.Unrestricted;

 // Load the assembly files
 clrAssembly.LoadFiles(Environment.CurrentDirectory
 + @"\StoredProcedures2.dll", false);

 clrAssembly.Update();
}
```

```
}
```

## Backup and Restore methods

The Backup and Restore methods let administrators back up databases and restore them.

The following sample creates backups for all databases in the specified server. If a backup file already exists, then it is overwritten. Backup files are saved in the BackUp folder in the Analysis Services Data folder.

```
C#
```

```
static public void BackUpAllDatabases(Server svr)
{
 string fileName;
 if ((svr != null) && (svr.Connected))
 foreach (Database db in svr.Databases)
 {
 fileName = db.Name + "_" + ((Int64)(DateTime.Today.Year * 10000
+ DateTime.Today.Month * 100 + DateTime.Today.Day)).ToString() + ".abf";
 db.Backup(fileName, true);
 }
}
```

The following sample restores the "Adventure Works" backup from the previous sample. If the "My Adventure WorksDW" database already exists, then the database is overwritten.

```
C#
```

```
static public void RestoreAdventureWorks(Server svr)
{
 svr.Restore("Adventure Works DW_20051025.abf", "My Adventure WorksDW",
true);
}
```

## Trace class

Monitoring the server activity requires using two kinds of traces: Session Traces and Server Traces. Tracing the server can tell you how your current task is performing on the server (Session Traces) or the traces can tell you about the overall activity in the server without you even being connected to the server (Server Traces).

When tracing current activity (Session Traces), the server sends notifications to the current application about the events that are occurring in the server that are caused by the application. Events are captured using event handlers in the current application. You first assign the event handling routines to the [SessionTrace](#) object and then start the Session Trace.

The following sample shows how to setup a Session Trace to trace current activities. Event handler routines are located at the end of the sample and will output all trace information to the `System.Console` object. To generate tracing events the "Adventure Works" sample cube will be fully processed after the trace starts.

C#

```
static public void TestSessionTraces(Server svr)
{
 // Start the default trace

 svr.SessionTrace.OnEvent
 += new TraceEventHandler(DefaultTrace_OnEvent);
 svr.SessionTrace.Stopped
 += new TraceStoppedEventHandler(DefaultTrace_Stopped);
 svr.SessionTrace.Start();

 // Process the databases
 // The trace handlers will output all progress notifications
 // to the console
 Database db = svr.Databases.FindByName("Adventure Works DW
Multidimensional 2012");
 Cube cube = db.Cubes.FindByName("Adventure Works");
 cube.Process(ProcessType.ProcessFull);

 // Stop the default trace
 svr.SessionTrace.Stop();

}

static public void DefaultTrace_OnEvent(object sender, TraceEventArgs e)
{
 Console.WriteLine("{0}", e.TextData);
}

static public void DefaultTrace_Stopped(ITrace sender, TraceStoppedEventArgs e)
{
 switch (e.StopCause)
 {
 case TraceStopCause.StoppedByUser:
 case TraceStopCause.Finished:
 Console.WriteLine("Processing completed successfully");
 break;

 case TraceStopCause.StoppedByException:
 }
}
```

```

 Console.WriteLine("Processing failed: {0}",
 e.Exception.Message);
 break;
 }
}

```

Server traces can be configured to log everything to a trace file and can be automatically restarted when the service restarts.

To set a server trace, you first need to define which events in the server to be monitored, and what data from the event should be saved in the trace file. For each event, you must define the data columns to be saved in the trace file.

Creating a server trace requires four steps:

1. Create the server trace object and populate basic common attributes.

LogFileSize defines the maximum size of the trace file and is defined in MegaBytes; LogFileRollOver enables the logfile to start on a different file if LogFileSize limit is reached, when enabled the file name is appended with a sequence namber; AutoRestart enables the trace to start again if the Service is restarted.

2. Create the events and the corresponding data columns.

3. Start and stop the trace as needed.

Even after the trace has been stopped, the trace exists in the server and should start again if the trace was defined as AutoRestart=true.

4. Drop the trace when no longer needed.

In the following sample, if the trace already exists, it is dropped and then recreated.

Trace files are saved in the Log folder of Analysis Services data folders.

C#

```

static public void TestServerTraces(Server svr)
{
 Trace trc;
 TraceEvent te;

 trc = svr.Traces.FindByName("TestServerTraces");
 if (trc != null)
 trc.Drop();
 trc = svr.Traces.Add("TestServerTraces", "TestServerTraces");
 trc.LogFileName = ("TestServerTraces_" + ((Int64)(DateTime.Now.Year *
10000 + DateTime.Now.Month * 100 + DateTime.Now.Day)).ToString() + "_" +
((Int64)(DateTime.Now.Hour * 10000 + DateTime.Now.Minute *
100 + DateTime.Now.Second)).ToString() + ".trc");

```

```

 trc.LogFileSize = 100;
 trc.LogFileRollover = true;
 trc.AutoRestart = false;

 #region Define Events to trace & data columns per event
 te = trc.Events.Add(TraceEventClass.ProgressReportBegin);
 te.Columns.Add(TraceColumn.TextData);
 te.Columns.Add(TraceColumn.StartTime);
 te.Columns.Add(TraceColumn.ObjectName);
 te.Columns.Add(TraceColumn.ObjectPath);
 te.Columns.Add(TraceColumn.DatabaseName);
 te.Columns.Add(TraceColumn.NTCanonicalUserName);

 te = trc.Events.Add(TraceEventClass.ProgressReportCurrent);
 te.Columns.Add(TraceColumn.TextData);
 te.Columns.Add(TraceColumn.CurrentTime);
 te.Columns.Add(TraceColumn.ObjectName);
 te.Columns.Add(TraceColumn.ObjectPath);
 te.Columns.Add(TraceColumn.DatabaseName);

 te = trc.Events.Add(TraceEventClass.ProgressReportEnd);
 te.Columns.Add(TraceColumn.TextData);
 te.Columns.Add(TraceColumn.StartTime);
 te.Columns.Add(TraceColumn.CurrentTime);
 te.Columns.Add(TraceColumn.EndTime);
 te.Columns.Add(TraceColumn.Success);
 te.Columns.Add(TraceColumn.Error);
 te.Columns.Add(TraceColumn.ObjectName);
 te.Columns.Add(TraceColumn.ObjectPath);
 te.Columns.Add(TraceColumn.DatabaseName);
 te.Columns.Add(TraceColumn.NTCanonicalUserName);
 #endregion

 trc.Update();
 trc.Start();

 #region Process the Adventure Works Cube
 // The trace settings will output all progress notifications
 // to the trace file
 Database db = svr.Databases.FindByName("Adventure Works DW
Multidimensional 2012");
 Cube cube = db.Cubes.FindByName("Adventure Works");
 cube.Process(ProcessType.ProcessFull);
 #endregion

 trc.Stop();
 trc.Drop();

 }

```

## CaptureLog and CaptureXml attributes

The CaptureLog attribute enables you to create XMLA batch files from your AMO operations. CaptureLog enables you to script out server objects as databases, cubes, dimensions, mining structures, and others.

Creating a CaptureLog requires the following steps:

1. Start capturing the XMLA log by setting the server attribute CaptureXml to **true**.

This option will start saving all AMO operations to a string collection instead of sending them to the server.

2. Start AMO activity as usual, but remember that no action is being sent to the server. Activity can be any operation such as processing, creating, deleting, updating, or any other action over an object.

3. Stop capturing the XMLA log by resetting CaptureXml to **false**.

4. Review the captured XMLA, either by reviewing each of the strings in the CaptureLog string collection, or by generating a complete string with the ConcatenateCaptureLog method. ConcatenateCaptureLog enables you to generate the XMLA batch as a single transaction and to add the parallel process option to the batch.

The following sample returns a string with the batch commands to do a Full process on all dimensions and on all cubes on the [Adventure Works DW Multidimensional 2012] database.

C#

```
static public string TestCaptureLog(Server svr)
{
 String capturedXmla = "";
 if ((svr != null) && (svr.Connected))
 {
 svr.CaptureXml = true;

 #region Actions to be captured to an XMLA file
 //No action is executed during CaptureXml = true
 Database db = svr.Databases.FindByName("Adventure Works DW
Multidimensional 2012");
 foreach (Dimension dim in db.Dimensions)
 dim.Process(ProcessType.ProcessFull);
 foreach (Cube cube in db.Cubes)
 cube.Process(ProcessType.ProcessFull);
 #endregion

 svr.CaptureXml = false;

 capturedXmla = svr.ConcatenateCaptureLog(true, true);
```

```
 }

 return capturedXmla;
}
```

# ADOMD.NET

Article • 10/31/2023

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

ADOMD.NET is a Microsoft .NET Framework data provider designed to communicate with Analysis Services. ADOMD.NET uses the XML for Analysis protocol to communicate with analytical data sources by using either TCP/IP or HTTP connections to transmit and receive SOAP requests and responses that are compliant with the XML for Analysis specification. Commands can be sent in Multidimensional Expressions (MDX), Data Mining Extensions (DMX), Analysis Services Scripting Language (ASSL), or even a limited syntax of SQL, and may not return a result. Analytical data, key performance indicators (KPIs), and mining models can be queried and manipulated by using the ADOMD.NET object model. By using ADOMD.NET, you can also view and work with metadata either by retrieving OLE DB-compliant schema rowsets or by using the ADOMD.NET object model.

The ADOMD.NET data provider is represented by the [Microsoft.AnalysisServices.AdomdClient](#) namespace.

# ADOMD.NET Client Functionality

Article • 10/31/2023

ADOMD.NET, as with other Microsoft .NET Framework data providers, serves as a bridge between an application and a data source. However, ADOMD.NET is unlike other .NET Framework data providers in that ADOMD.NET works with analytical data. To work with analytical data, ADOMD.NET supports functionality that is very different than other .NET Framework data providers. ADOMD.NET not only allows you to retrieve data, but also to retrieve metadata and change the structure of the analytical data store:

## Retrieving Metadata

Applications can learn more about the data that can be retrieved from the data source through metadata retrieval, using either schema rowsets or the object model.

Information such as the types of each key performance indicator (KPI) that are available, the dimensions in a cube, and the parameters needed by the mining models are all discoverable. Metadata is most important to *dynamic* applications that require user input to determine the type, depth, and scope of data to be retrieved. Examples include Query Analyzer, Microsoft Excel, and other querying tools. Metadata is less critical to *static* applications that perform a predefined set of actions.

For more information: [Retrieving Metadata from an Analytical Data Source](#).

## Retrieving Data

Data retrieval is the actual retrieval of the information stored in the data source. Data retrieval is the primary function of "static" applications, which know the structure of the data source. Data retrieval is also the end result of "dynamic" applications. The value of the KPI at a given time of day, the number of bicycles sold within the last hour for each store, and the factors governing the annual performance of employees are all examples of data that can be retrieved. Retrieving data is vital for any querying application.

For more information: [Retrieving Data from an Analytical Data Source](#).

## Changing the Structure of Analytical Data

ADOMD.NET can also be used to actually change the structure of the analytical data store. Though this is usually done through the Analysis Management Objects (AMO) object model, you can use ADOMD.NET to send Analysis Services Scripting Language (ASSL) commands to create, alter, or delete objects on the server.

Retrieving metadata, retrieving data, and changing data structure each occur at a specific point in the workflow of a typical ADOMD.NET application.

# Typical Process Flow

Traditional ADOMD.NET applications usually follow the same workflow when working with an analytical database:

1. First, a connection is made to the database, using the [AdomdConnection](#) object. When you open the connection, the [AdomdConnection](#) object exposes metadata about the server to which you have connected. In a dynamic application, some of this information is typically shown to the user so that the user can make a selection, such as which cube to query. The connection created during this step can be reused multiple times by the application, reducing overhead.

For more information: [Establishing Connections in ADOMD.NET](#)

2. Once a connection has been made, a dynamic application would then query the server for more specific metadata. For a static application, the programmer knows in advance which objects the application will be querying, and thus will not need to retrieve this metadata. Metadata that is retrieved can be used by the application and the user for the next step.

For more information: [Retrieving Metadata from an Analytical Data Source](#)

3. The application then runs a command against the server. This command can be for the purpose of retrieving additional metadata, retrieving data, or modifying the database structure. For any of these tasks, the application could use a previously-determined query, or make use of newly retrieved metadata to create additional queries.

For more information: [Retrieving Metadata from an Analytical Data Source](#), [Retrieving Data from an Analytical Data Source](#), [Executing Commands Against an Analytical Data Source](#)

4. Once the command has been sent to the server, the server begins to return the metadata or data to the client. This information can be viewed by using a [CellSet](#) object, an [AdomdDataReader](#) object, or a [System.XmlReader](#) object.

To illustrate this traditional workflow, the following example contains a method that opens a connection to the database, executes a command against a known cube, and retrieves the results into a cellset. The cellset then returns a tab-delimited string containing column headers, row headers, and cell data.

cs

```

string ReturnCommandUsingCellSet()
{
 //Create a new string builder to store the results
 System.Text.StringBuilder result = new System.Text.StringBuilder();

 //Connect to the local server
 using (AdomdConnection conn = new AdomdConnection("Data
Source=localhost;"))
 {
 conn.Open();

 //Create a command, using this connection
 AdomdCommand cmd = conn.CreateCommand();
 cmd.CommandText = @"
 WITH MEMBER [Measures].[FreightCostPerOrder] AS
 [Measures].[Reseller Freight Cost]/[Measures].
[Reseller Order Quantity],
 FORMAT_STRING = 'Currency'
 SELECT
 [Geography].[Geography].[Country].&[United
States].Children ON ROWS,
 [Date].[Calendar].[Calendar Year] ON COLUMNS
 FROM [Adventure Works]
 WHERE [Measures].[FreightCostPerOrder]";

 //Execute the query, returning a cellset
 CellSet cs = cmd.ExecuteCellSet();

 //Output the column captions from the first axis
 //Note that this procedure assumes a single member exists per
column.
 result.Append("\t");
 TupleCollection tuplesOnColumns = cs.Axes[0].Set.Tuples;
 foreach (Tuple column in tuplesOnColumns)
 {
 result.Append(column.Members[0].Caption + "\t");
 }
 result.AppendLine();

 //Output the row captions from the second axis and cell data
 //Note that this procedure assumes a two-dimensional cellset
 TupleCollection tuplesOnRows = cs.Axes[1].Set.Tuples;
 for (int row = 0; row < tuplesOnRows.Count; row++)
 {
 result.Append(tuplesOnRows[row].Members[0].Caption + "\t");
 for (int col = 0; col < tuplesOnColumns.Count; col++)
 {
 result.Append(cs.Cells[col, row].FormattedValue + "\t");
 }
 result.AppendLine();
 }
 conn.Close();

 return result.ToString();
 }
}

```

```
 } // using connection
}
```

# ADOMD.NET Client Programming

Article • 10/31/2023

The ADOMD.NET client components reside within the **Microsoft.AnalysisServices.AdomdClient** namespace (in `microsoft.analysisservices.adomdclient.dll`). These client components provide the functionality for client and middle-tier applications to easily query data and metadata from an analytical data store, such as Microsoft SQL Server Analysis Services.

## Using the ADOMD.NET Client Objects

In querying an analytical data source, there are a set of common tasks that need to be performed. The following table represents the common tasks in which you use the ADOMD.NET client objects to perform such a query.

[+] Expand table

Task	Description
Establishing Connections in ADOMD.NET	In ADOMD.NET, you use an <a href="#">AdomdConnection</a> object to establish connections with analytical data sources, such as Analysis Services databases. You can use the <a href="#">AdomdConnection</a> object to run commands, retrieve data, and retrieve metadata from the analytical data source.
Retrieving Metadata from an Analytical Data Source	After a connection has been established, you can use a wide variety of objects to retrieve information about the underlying data source. This functionality allows applications to adapt to the data source to which they have connected.
Executing Commands Against an Analytical Data Source	The <a href="#">AdomdCommand</a> object provides the interfaces necessary for running commands against the underlying analytical data source.
Retrieving Data from an Analytical Data Source	After a command runs, data could be retrieved and parsed using either the <a href="#">CellSet</a> , <a href="#">AdomdDataReader</a> , or <a href="#">System.XmlReader</a> objects.
Performing Transactions in ADOMD.NET	All of the actions listed in the previous rows of this table can take place within a read-committed transaction, in which shared locks are held while the data is being read to avoid dirty reads. The data can still be changed before the end of the transaction, resulting in non-repeatable reads or phantom data. The <a href="#">AdomdTransaction</a> object provides the transaction functionality in ADOMD.NET.

Interaction with the ADOMD.NET object hierarchy typically starts with one or more of the objects in the topmost layer, as described in the following table.

[+] Expand table

To	Use this object
Connect to an analytical data source	<p><a href="#">AdomdConnection</a></p> <p>The <a href="#">AdomdConnection</a> object represents both a connection to a data source and the data source metadata. For example, you can connect to a Microsoft SQL Server Analysis Services local cube (.cub) file, and then examine the <a href="#">Cubes</a> property to obtain metadata about the cubes present on the analytical data source. This object also represents the implementation of the <a href="#">IDbConnection</a> interface, an interface that is required by all .NET Framework data providers.</p>
Discover the data mining capabilities of the data source	<p><a href="#">AdomdConnection</a></p> <p>The <a href="#">AdomdConnection</a> object exposes several mining collections:</p> <p>The <a href="#">MiningModelCollection</a> contains a list of every mining model in the data source.</p> <p>The <a href="#">MiningServiceCollection</a> provides information about the available mining algorithms.</p> <p>The <a href="#">MiningStructureCollection</a> exposes information about the mining structures on the server.</p>
Query the data source	<p><a href="#">AdomdCommand</a></p> <p>The <a href="#">AdomdCommand</a> object represents the statement or query that will be sent to the server. Once a connection is established to a data source, you use a <a href="#">AdomdCommand</a> object to run statements in the supported language, such as Multidimensional Expressions (MDX) or Data Mining Data Mining Extensions (DMX). You can also use a <a href="#">AdomdCommand</a> object to return results in the form of <a href="#">CellSet</a> or <a href="#">AdomdDataReader</a> objects.</p>
Retrieve data in a fast, efficient way	<p><a href="#">AdomdDataReader</a></p> <p>The <a href="#">AdomdDataReader</a> can be created with a call to the</p>

To	Use this object
	<p>Execute or ExecuteReader method of an <a href="#">AdomdCommand</a> object. This object implements the <a href="#">IDbDataReader</a> interface from the <a href="#">System.Data</a> namespace of the .NET Framework class library.</p>
Retrieve analytical data with the highest amount of metadata	<p><a href="#">CellSet</a></p> <p>The <a href="#">CellSet</a> can be created with a call to the <a href="#">Execute</a> or <a href="#">ExecuteCellSet</a> method of an <a href="#">AdomdCommand</a>. Once an <a href="#">AdomdCommand</a> has returned a <a href="#">CellSet</a>, you can then examine the analytical data contained by the <a href="#">CellSet</a>.</p>
Retrieve metadata about cubes, such as available dimensions, measures, named sets, and so on	<p><a href="#">CubeDef</a></p> <p>The <a href="#">CubeDef</a> represents metadata about a cube. You reference the <a href="#">CubeDef</a> from the <a href="#">AdomdConnection</a>.</p>
Retrieve data using the <a href="#">System.Data.IDbDataAdapter</a> interface	<p><a href="#">AdomdDataAdapter</a></p> <p>The <a href="#">AdomdDataAdapter</a> provides read-only support for existing .NET Framework client applications.</p>

# Connections in ADOMD.NET - Establishing Secure Connections

Article • 10/31/2023

When you use a connection in ADOMD.NET, the security method that is used for the connection depends on the value of the **ProtectionLevel** property of the connection string used when you call the [Open](#) method of the [AdomdConnection](#).

The **ProtectionLevel** property offers four levels of security: unauthenticated, authenticated, signed, and encrypted. The following table describes these various security levels.

## ⓘ Note

If you choose to use database connection pooling, the database will not be able to manage security. This is because database connection pooling requires that the connection string be identical to pool connections. Therefore, you must manage security elsewhere.

[+] Expand table

Security Level	ProtectionLevel Value
<i>unauthenticated connection</i> An unauthenticated connection does no form of authentication. This kind of connection represents the most widely supported, but least secure, form of connection.	None
<i>authenticated connection</i> An authenticated connection authenticates the user who is making the connection, but does not secure additional communications. This kind of connection is useful in that you can establish the identity of the user or application that is connecting to an analytical data source.	Connect
<i>signed connection</i> A signed connection authenticates the user who is requesting the connection, and then makes sure that transmissions are not modified. This kind of connection is useful when the authenticity of the transferred data must be verified. However, a signed connection only prevents the content of the data packet from being modified. The content can still be viewed in transit.	Pkt Integrity or PktIntegrity

Security Level	ProtectionLevel Value
<p>Note that a signed connection is only supported by the XML for Analysis provider supplied by Microsoft SQL Server Analysis Services.</p>	
<p><i>encrypted connection</i></p> <p>An encrypted connection is the default connection type used by ADOMD.NET. This kind of connection authenticates the user who is requesting the connection, and then also encrypts the data that is transmitted. An encrypted connection is the securest form of connection that can be created by ADOMD.NET. The content of the data packet cannot be viewed or modified, thereby protecting data during transit.</p>	<p>Pkt Privacy or PktPrivacy</p>
<p>An encrypted connection is only supported by the XML for Analysis provider supplied by SQL Server Analysis Services.</p>	

However, not all levels of security are available for all kinds of connections:

- A TCP connection can use any one of the four levels of security. In fact, a TCP connection, when you use it with Windows Integrated Security, offers the securest method of connecting to an analytical data source.
- An HTTP connection can only be an authenticated connection. Therefore, the **ProtectionLevel** property must be set to **Connect**.
- An HTTPS connection can only be an encrypted connection. Therefore, the **ProtectionLevel** property must be set to **Pkt Privacy** or **PktPrivacy**.

## Securing TCP Connections

For a TCP connection, the **ProtectionLevel** property supports all four levels of security, as shown in the following table.

[\[+\] Expand table](#)

ProtectionLevel Value	Use with TCP Connection?	Results
None	Yes	<p>Specifies an unauthenticated connection.</p> <p>A TCP stream is requested from the provider, but there is no</p>

<b>ProtectionLevel Value</b>	<b>Use with TCP Connection?</b>	<b>Results</b>
		form of authentication performed on the user who is requesting the stream.
Connect	Yes	<p>Specifies an authenticated connected.</p> <p>A TCP stream is requested from the provider, and then the security context of the user who is requesting the stream is authenticated against the server: If authentication succeeds, no other action is taken. If authentication fails, the <a href="#">AdomdConnection</a> object disconnects from the multidimensional data source and an exception is thrown.</p> <p>After authentication succeeds or fails, the security context that is used to authenticate the connection is disposed.</p>
Pkt Integrity or PktIntegrity	Yes	<p>Specifies a signed connection.</p> <p>A TCP stream is requested from the provider, and then the security context of the user who is requesting the stream is authenticated against the server:</p> <p>If authentication succeeds, the <a href="#">AdomdConnection</a> object closes the existing TCP stream and opens a signed TCP stream to handle all requests. Each request for data or metadata is authenticated by using the security context that was used to open the connection. Additionally, each packet is digitally signed to make sure that the payload of the TCP packet has not been changed in any way.</p> <p>If authentication fails, the <a href="#">AdomdConnection</a> object disconnects from the multidimensional data source and an exception is thrown.</p>
Pkt Privacy or PktPrivacy	Yes	<p>Specifies an encrypted connection.</p> <p>Note that you can also specify an encrypted connection by not setting the <b>ProtectionLevel</b> property in the connection string.</p>

<b>ProtectionLevel</b>	<b>Use with TCP Connection?</b>	<b>Results</b>
<b>Value</b>		
		A TCP stream is requested from the provider, and then the security context of the user requesting the stream is authenticated against the server:
		If authentication succeeds, the <a href="#">AdomdConnection</a> object closes the existing TCP stream and opens up an encrypted TCP stream to handle all requests. Each request for data or metadata is authenticated by using the security context that was used to open the connection. Additionally, the payload of each TCP packet is encrypted by using the highest encryption method supported by both the provider and the multidimensional data source.
		If authentication fails, the <a href="#">AdomdConnection</a> object disconnects from the multidimensional data source and an exception is thrown.

## Using Windows Integrated Security for the Connection

Windows Integrated Security is the securest way of establishing and securing a connection to an instance of Analysis Services. Windows Integrated Security does not reveal security credentials, such as a user name or password, during the authentication process, but instead uses the security identifier of the currently running process to establish identity. For most client applications, this security identifier represents the identity of the currently logged-on user.

To use Windows Integrated Security, the connection string requires the following settings:

- For the **Integrated Security** property, either do not set this property or set this property to **SSPI**.

### ① Note

Windows Integrated Security is only available for TCP connections because HTTP connections must use the **Basic** setting for the **Integrated Security** property.

- For the **ProtectionLevel** property, set this property to **Connect**, **Pkt Integrity**, or **Pkt Privacy**.

## Securing HTTP Connections

HTTPS and Secure Sockets Layer (SSL) can be used to externally secure HTTP communications with an analytical data source.

Because an XMLA provider only uses secure HTTP, an HTTP connection in ADOMD.NET must be a signed connection, as shown in the following table.

[\[+\] Expand table](#)

ProtectionLevel Value	Use with HTTP or HTTPS
None	No
Connect	HTTP
Pkt Integrity or PktIntegrity	No
Pkt Privacy or PktPrivacy	HTTPS

## Opening a Secure HTTP Connection

The following example demonstrates how to use ADOMD.NET to open an HTTP connection for the **AdventureWorksAS** sample Analysis Services database:

VB

```
Public Function GetAWEncryptedConnection(_
 Optional ByVal serverName As String = _
 "https://localhost/isapy/msmdpump.dll") _
 As AdomdConnection

 Dim strConnectionString As String = ""
 Dim objConnection As New AdomdConnection

 Try
 ' To establish an encrypted connection, set the
 ' ProtectionLevel setting to PktPrivacy.
 strConnectionString = "DataSource=" & serverName & ";" & _
 "Catalog=AdventureWorksAS;" & _
 "ProtectionLevel=PktPrivacy;"

 ' Note that username and password are not supplied here.
 ' The current security context is used for authentication
 ' purposes.
 End Try
End Function
```

```
 objConnection.ConnectionString = strConnectionString
 objConnection.Open()
Catch ex As Exception
 objConnection = Nothing
 Throw ex
Finally
 ' Return the encrypted connection.
 GetAWEncryptedConnection = objConnection
End Try
End Function
```

---

# Connections in ADOMD.NET - Performing Transactions

Article • 10/31/2023

In ADOMD.NET, you use the [AdomdTransaction](#) object to manage transaction context for a given [AdomdConnection](#) object. This functionality allows you to run several commands within the same context. Each command will read the same data without the read data changing between each command execution.

## ⓘ Note

The [AdomdTransaction](#) class is the implementation of the [System.Data.IDbTransaction](#) interface, part of the Microsoft .NET Framework Class Library and implemented by all .NET Framework data providers that support transactions.

The [AdomdTransaction](#) object only supports read-committed transactions, in which shared locks are held while the data is being read to avoid dirty reads.

The [AdomdConnection](#) is used to start the transaction. To use the transaction, commands are then run against the connection that started the transaction. When you are finished with the transaction, you can either be roll back or commit the transaction.

## Starting a Transaction

You create an instance of an [AdomdTransaction](#) object by calling the [BeginTransaction](#) method of the [AdomdConnection](#) object. The following example shows how to create an instance of the [AdomdTransaction](#) object:

VB

```
Dim objTransaction As AdomdTransaction = objConnection.BeginTransaction()
AdomdTransaction objTransaction = objConnection.BeginTransaction();
```

## Rolling Back a Transaction

To roll back an existing, incomplete transaction, you call the [Rollback](#) method of the [AdomdTransaction](#) object. If you call this method on an existing, complete transaction, an exception is thrown.

# Committing a Transaction

After you call the [BeginTransaction](#) method to start a transaction, you can complete the transaction by calling the [Commit](#) method of the [AdomdTransaction](#) object. If this method is called on an existing, complete transaction, an exception is thrown.

# Connections in ADOMD.NET - Working with Connections and Sessions

Article • 10/31/2023

In XML for Analysis (XMLA), sessions provide support for stateful operations during analytical data access. Sessions frame the scope and context of commands and transactions for an analytical data source. The XMLA elements used to manage sessions are BeginSession, Session, and EndSession.

ADOMD.NET uses these three XMLA session elements when you start a session, perform queries or retrieve data during the session, and close a session.

## Starting a Session

The [SessionID](#) property of the [AdomdConnection](#) object contains the identifier of the active session associated with the [AdomdConnection](#) object. By using this property correctly, you can effectively control both client and server statefulness in your application:

- If the [SessionID](#) property is not set to a valid session ID when the [Open](#) method is called, the [AdomdConnection](#) object requests a new session ID from the provider. ADOMD.NET initiates a session by sending an XMLA **BeginSession** header to the provider. If ADOMD.NET is successful in starting a session, ADOMD.NET sets the value of the [SessionID](#) property to the session ID of the newly created session.
- If the [SessionID](#) property is set to a valid session ID when the [Open](#) method is called, the [AdomdConnection](#) object tries to connect to the specified session.

If the [AdomdConnection](#) object cannot connect to the specified session, or if the provider does not support sessions, an exception is thrown.

### Note

After you have had ADOMD.NET create a session, you can connect multiple [AdomdConnection](#) objects to that single active session, or you can disconnect a single [AdomdConnection](#) object from that session and reconnect that object to another session.

## Working in a Session

After ADOMD.NET connects the [AdomdConnection](#) object to a valid session, ADOMD.NET will send an XMLA **Session** header to the provider with every request for data or metadata made by an application. Every request will have the session ID set to the value of the [SessionID](#) property.

A session ID does not guarantee that a session remains valid. If the session expires (for example, if the session times out or the connection is lost), the provider can choose to end and roll back the actions of that session. If this occurs, all subsequent method calls from the [AdomdConnection](#) object will throw an exception. Because exceptions are thrown only when the next request is sent to the provider, not when the session expires, your application must be able to handle these exceptions any time that your application retrieves data or metadata from the provider.

## Closing a Session

If the [Close](#) method is called without specifying the value of the *endSession* parameter, or if the *endSession* parameter is set to True, both the connection to the session and the session associated with the [AdomdConnection](#) object are closed. To close a session, ADOMD.NET sends an XMLA **EndSession** header to the provider, with the session ID set to the value of the [SessionID](#) property.

If the [Close](#) method is called with the *endSession* parameter set to False, the session associated with the [AdomdConnection](#) object remains active but the connection to the session is closed.

## Example of Managing a Session

The following example demonstrates how to open a connection, create a session, and close the connection while keeping the session open in ADOMD.NET:

VB

```
Public Function CreateSession(ByVal connectionString As String) As String
 Dim strSessionID As String = ""
 Dim objConnection As New AdomdConnection

 Try
 ' First, try to connect to the specified data source.
 ' If the connection string is not valid, or if the specified
 ' provider does not support sessions, an exception is thrown.
 objConnection.ConnectionString = connectionString
 objConnection.Open()

 ' Now that the connection is open, retrieve the new
```

```
' active session ID.
strSessionID = objConnection.SessionID
' Close the connection, but leave the session open.
objConnection.Close(False)
Return strSessionID

Finally
 objConnection = Nothing
End Try
End Function
```

C#

```
static string CreateSession(string connectionString)
{
 string strSessionID = "";
 AdomdConnection objConnection = new AdomdConnection();
 try
 {
 /*First, try to connect to the specified data source.
 If the connection string is not valid, or if the specified
 provider does not support sessions, an exception is thrown. */
 objConnection.ConnectionString = connectionString;
 objConnection.Open();

 // Now that the connection is open, retrieve the new
 // active session ID.
 strSessionID = objConnection.SessionID;
 // Close the connection, but leave the session open.
 objConnection.Close(false);
 return strSessionID;
 }
 finally
 {
 objConnection = null;
 }
}
```

# Connections in ADOMD.NET

Article • 10/31/2023

In ADOMD.NET, you use the [AdomdConnection](#) object to open connections with analytical data sources, such as Microsoft SQL Server Analysis Services databases. When the connection is no longer needed, you should explicitly close the connection.

## Opening a Connection

To open a connection in ADOMD.NET, you must first specify a connection string to a valid analytical data source and database. Then, you must explicitly open the connection to that data source.

## Specifying a Multidimensional Data Source

To specify an analytical data source and database, you set the [ConnectionString](#) property of the [AdomdConnection](#) object. The connection string specified for the [ConnectionString](#) property is an OLE DB-compliant string. ADOMD.NET uses the specified connection string to determine how to connect to the server.

The [ConnectionString](#) property can be set on either an existing [AdomdConnection](#) object or during the creation an instance of an [AdomdConnection](#) object. The following code demonstrates how to set the [ConnectionString](#) property when you create an ADOMD connection:

VB

```
Dim advwrksConnection As New AdomdConnection("Data
Source=localhost;Catalog=AdventureWorksAS")
System.Diagnostics.Debug.WriteLine(advwrksConnection.ConnectionString)
```

C#

```
AdomdConnection advwrksConnection = new AdomdConnection("Data
Source=localhost;Catalog=AdventureWorksAS");
System.Diagnostics.Debug.WriteLine(advwrksConnection.ConnectionString);
```

## Opening a Connection to the Data Source

After you have specified the connection string, you must use the [Open](#) method to open the connection. When you open a [AdomdConnection](#) object, you can set various levels of security for the connection. The security level that is used for the connection depends on the value of the **ProtectionLevel** connection string setting. For more information about opening secure connections in ADOMD.NET, see [Establishing Secure Connections in ADOMD.NET](#).

## Working with a Connection

Each open connection exists in a session, which provides support for stateful operations. A session can be shared by more than one open connection. Sharing a session enables more than one client to share the same context. For more information, see [Working with Connections and Sessions in ADOMD.NET](#).

You can use an open connection to retrieve metadata, data, and run commands. For more information, see [Retrieving Metadata from an Analytical Data Source](#), [Retrieving Data from an Analytical Data Source](#), and [Executing Commands Against an Analytical Data Source](#).

When the connection is open, you can retrieve data, retrieve metadata, and run commands from within a read-committed transaction, in which shared locks are held while the data is being read to avoid dirty reads. The data can still be changed before the end of the transaction, resulting in non-repeatable reads or phantom data. For more information, see [Performing Transactions in ADOMD.NET](#).

## Closing a Connection

We recommend that you explicitly close an [AdomdConnection](#) object as soon as you no longer need the connection. To explicitly close the connection, you use the **Close** and **Dispose** methods of the [AdomdConnection](#) object.

A connection that is not explicitly closed, but is allowed to fall out of scope, may not release server resources quickly enough to enable high-concurrency Analysis Services client applications to efficiently open new connections. Depending on how you created the connection, the session used by the [AdomdConnection](#) object can remain active if the connection is not explicitly closed.

For more information about sessions, see [Working with Connections and Sessions in ADOMD.NET](#).

 **Important**

In the **Finalize** method of any implemented class, do not call the **Close** or **Dispose** methods of an [AdomdConnection](#) object, [AdomdDataReader](#) object, or any other managed object. In a finalizer, only release unmanaged resources that are directly owned by the implemented class. If the implemented class does not own any unmanaged resources, do not include a **Finalize** method in the class definition.

# Executing Commands Against an Analytical Data Source

Article • 10/31/2023

After establishing a connection to an analytical data source, you can use an [AdomdCommand](#) object to run commands against and return results from that data source. These commands can retrieve data by using Multidimensional Expressions (MDX), Data Mining Extensions (DMX), or even a limited syntax of SQL. Additionally, you can use Analysis Services Scripting Language (ASSL) commands to modify the underlying database.

## Creating a Command

Before running a command, you must create it. You can create a command using one of two methods:

- The first method uses the [AdomdCommand](#) constructor, which can take a command to run at the data source, and an [AdomdConnection](#) object on which to run the command.
- The second method uses the [CreateCommand](#) method of the [AdomdConnection](#) object.

The text of the command to be run can be queried and modified using the [CommandText](#) property. The commands that you create do not have to return data after they run.

## Running a Command

After you have created an [AdomdCommand](#) object, there are several [Execute](#) methods that your command can use to perform various actions. The following table lists some of these actions.

[+] Expand table

To	Use this method
Return results as a stream of data	<a href="#">ExecuteReader</a> to return an <a href="#">AdomdDataReader</a> object

To	Use this method
Return a <b>CellSet</b> object	<a href="#">ExecuteCellSet</a>
Run commands that do not return rows	<a href="#">ExecuteNonQuery</a>
Return an <b>XMLReader</b> object that contains the data in an XML for Analysis (XMLA) compliant format	<a href="#">ExecuteXmlReader</a>

## Example of Running a Command

This example uses the [AdomdCommand](#) to run an XMLA command that will process the **Adventure Works DW** cube on the local server, without returning data.

```
cs

 void ExecuteXMLAProcessCommand()
 {
 //Open a connection to the local server
 AdomdConnection conn = new AdomdConnection("Data
Source=localhost");
 conn.Open();

 //Create a command, and assign it an XMLA command to process the
 cube.
 AdomdCommand cmd = conn.CreateCommand();
 cmd.CommandText = "<Process
xmlns=\"http://schemas.microsoft.com/analysisservices/2003/engine\">\r\n" +
 @"<Object>
 <DatabaseID>Adventure Works DW Standard Edition</DatabaseID>
 <CubeID>Adventure Works DW</CubeID>
 </Object>
 <Type>ProcessFull</Type>
 <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
 </Process>";

 //Execute the command
 int result = cmd.ExecuteNonQuery();

 //Close the connection
 conn.Close();
 }
}
```

# Migrating From ADO MD To ADOMD.NET

Article • 10/31/2023

The ADOMD.NET library is similar to the ActiveX Data Objects Multidimensional (ADO MD) library, an extension of the ActiveX Data Objects (ADO) library that is used to access multidimensional data in Component Object Model (COM)-based client applications. ADO MD provides easy access to multidimensional data from unmanaged languages such as C++ and Microsoft Visual Basic. ADOMD.NET provides easy access to analytical (both multidimensional and data mining) data from managed languages such as Microsoft C# and Microsoft Visual Basic .NET. Additionally, ADOMD.NET provides an enhanced metadata object model.

Migrating existing client applications from ADO MD to ADOMD.NET is easy, but there are several important differences regarding migration:

## To provide connectivity and data access to client applications

[ ] [Expand table](#)

ADO MD	ADOMD.NET
Requires references to both Adodb.dll and Adomd.dll.	Requires a single reference to Microsoft.AnalysisServices.AdomdClient.dll.

The [AdomdConnection](#) class provides connectivity support, in addition to access to metadata.

## To retrieve metadata for multidimensional objects

[ ] [Expand table](#)

ADO MD	ADOMD.NET
Use the Catalog class.	Use the <a href="#">Cubes</a> property of the <a href="#">AdomdConnection</a> .

## To run queries and return cellset objects

[ ] [Expand table](#)

ADO MD	ADOMD.NET
Use the CellSet class.	Use the <a href="#">AdomdCommand</a> class.

To access the metadata that is used to display a cellset

[+] Expand table

ADO MD	ADOMD.NET
Use the Position class.	Use the <a href="#">Set</a> and <a href="#">Tuple</a> objects.

### (!) Note

The [Position](#) class is supported for backward compatibility.

To retrieve mining model metadata

In ADO MD there are no classes available. In ADOMD.NET use one of the data mining collections:

- The [MiningModelCollection](#) contains a list of every mining model in the data source.
- The [MiningServiceCollection](#) provides information about the available mining algorithms.
- The [MiningStructureCollection](#) exposes information about the mining structures on the server.

To highlight these differences the following migration example compares an existing ADO MD application to an equivalent ADOMD.NET application.

## Looking at a Migration Example

Both the existing ADO MD and equivalent ADOMD.NET code examples shown in this section perform the same set of actions: creating a connection, running a Multidimensional Expressions (MDX) statement, and retrieving metadata and data. However, these two sets of code do not use the same objects to perform those tasks.

### Existing ADO MD Code

The following code example, drawn from ADO MD 2.8 documentation, is written in Microsoft Visual Basic® 6.0 and uses ADO MD to demonstrate how to connect to and query a Microsoft SQL Server data source. This ADO MD example uses the following objects:

- Creates a connection from a **Catalog** object.
- Runs the Multidimensional Expressions (MDX) statement using the **Cellset** object.
- Retrieves the metadata and data from the **Position** object, retrieved from the **Cellset** object.

VB

```
Private Sub cmdCellSettoDebugWindow_Click()
Dim cat As New ADOMD.Catalog
Dim cst As New ADOMD.Cellset
Dim i As Integer
Dim j As Integer
Dim k As Integer
Dim strServer As String
Dim strSource As String
Dim strColumnHeader As String
Dim strRowText As String

On Error GoTo Error_cmdCellSettoDebugWindow_Click
Screen.MousePointer = vbHourglass
'*
'* Set server to local host.
'*
 strServer = "LOCALHOST"
'*
'* Set MDX query string source.
'*
 strSource = strSource & "SELECT "
 strSource = strSource & "{[Measures].members} ON COLUMNS,"
 strSource = strSource & _
 "NON EMPTY [Store].[Store City].members ON ROWS"
 strSource = strSource & " FROM Sales"

'*
'* Set active connection.
'*
 cat.ActiveConnection = "Data Source=" & strServer & _
 ";Provider=msolap;"

'*
'* Set cellset source to MDX query string.
'*
 cst.Source = strSource
```

```

'*-----*
'* Set cellset active connection to current connection
'*-----*
 Set cst.ActiveConnection = cat.ActiveConnection

'*-----*
'* Open cellset.
'*-----*
 cst.Open

'*-----*
'* Allow space for row header text.
'*-----*
strColumnHeader = vbTab & vbTab & vbTab & vbTab & vbTab & vbTab

'*-----*
'* Loop through column headers.
'*-----*
 For i = 0 To cst.Axes(0).Positions.Count - 1
 strColumnHeader = strColumnHeader & _
 cst.Axes(0).Positions(i).Members(0).Caption & vbTab & _
 vbTab & vbTab & vbTab
 Next
 Debug.Print vbTab & strColumnHeader & vbCrLf

'*-----*
'* Loop through row headers and provide data for each row.
'*-----*
 strRowText = ""
 For j = 0 To cst.Axes(1).Positions.Count - 1
 strRowText = strRowText & _
 cst.Axes(1).Positions(j).Members(0).Caption & vbTab & _
 vbTab & vbTab & vbTab
 For k = 0 To cst.Axes(0).Positions.Count - 1
 strRowText = strRowText & cst(k, j).FormattedValue & _
 vbTab & vbTab & vbTab & vbTab
 Next
 Debug.Print strRowText & vbCrLf
 strRowText = ""
 Next

 Screen.MousePointer = vbDefault
Exit Sub

Error_cmdCellSettoDebugWindow_Click:
 Beep
 Screen.MousePointer = vbDefault
 MsgBox "The following error has occurred:" & vbCrLf & _
 Err.Description, vbCritical, " Error!"
 Exit Sub
End Sub

```

## Equivalent ADOMD.NET Code

The following example, written in Visual Basic .NET and using ADOMD.NET, demonstrates how to perform the same actions as the previous Visual Basic 6.0 example. The major difference between the following example and the ADO MD example shown earlier is the objects that are used to perform the actions. The ADOMD.NET example uses the following objects:

- Creates a connection with an **AdomdConnection** object.
- Runs the MDX statement using an **AdomdCommand** object.
- Retrieves the metadata and data from the **Set** object, retrieved from the **Cellset** object.

```
VB

Private Sub DisplayCellSetInOutputWindow()
 Dim conn As AdomdConnection
 Dim cmd As AdomdCommand
 Dim cst As CellSet
 Dim i As Integer
 Dim j As Integer
 Dim k As Integer
 Dim strServer As String = "LOCALHOST"
 Dim strSource As String = "SELECT [Measures].members ON COLUMNS, " & _
 "NON EMPTY [Store].[Store City].members ON ROWS FROM SALES"
 Dim strOutput As New System.IO.StringWriter

 '-----
 ' * Open connection.
 '-----

 Try
 ' Create a new AdomdConnection object, providing the connection
 ' string.
 conn = New AdomdConnection("Data Source=" & strServer & _
 ";Provider=msolap;")
 ' Open the connection.
 conn.Open()
 Catch ex As Exception
 Throw New ApplicationException(_
 "An error occurred while connecting.")
 End Try

 Try
 '-----
 ' * Open cellset.
 '-----

 ' Create a new AdomdCommand object, providing the MDX query string.
 cmd = New AdomdCommand(strSource, conn)
```

```

 ' Run the command and return a CellSet object.
 cst = cmd.ExecuteCellSet()

 '-----*
 '-----*
 '-----*
 '-----*

 ' Include spacing to account for row headers.
 strOutput.WriteLine(vbTab, 6)

 ' Iterate through the first axis of the CellSet object and
 ' retrieve column headers.
 For i = 0 To cst.Axes(0).Set.Tuples.Count - 1
 strOutput.WriteLine(cst.Axes(0).Set.Tuples(i).Members(0).Caption)
 strOutput.WriteLine(vbTab, 4)
 Next
 strOutput.WriteLine()

 ' Iterate through the second axis of the CellSet object and
 ' retrieve row headers and cell data.
 For j = 0 To cst.Axes(1).Set.Tuples.Count - 1
 ' Append the row header.
 strOutput.WriteLine(cst.Axes(1).Set.Tuples(j).Members(0).Caption)
 strOutput.WriteLine(vbTab, 4)

 ' Append the cell data for that row.
 For k = 0 To cst.Axes(0).Set.Tuples.Count - 1
 strOutput.WriteLine(cst.Cells(k, j).FormattedValue)
 strOutput.WriteLine(vbTab, 4)
 Next
 strOutput.WriteLine()
 Next

 ' Display the output.
 Debug.WriteLine(strOutput.ToString())

 '-----*
 '-----*
 '-----*
 '-----*

 ' Release resources.
 '-----*
 '-----*
 '-----*
 conn.Close()
Catch ex As Exception
 ' Ignore or handle errors.
Finally
 cst = Nothing
 cmd = Nothing
 conn = Nothing
End Try
End Sub

```

# Retrieving Data from an Analytical Data Source

Article • 10/31/2023

Once you make a connection and create the query, you can retrieve any data. In ADOMD.NET, you can retrieve data using three different objects ([CellSet](#), [AdomdDataReader](#), and [XmlReader](#)) by calling one of the **Execute** methods of the [AdomdCommand](#) object.

Each of these three objects balances interactivity and overhead:

- *Interactivity* refers to the ease-of-use and amount of information available through the object model.
- *Overhead* refers to the amount of traffic that an object model generates over the network connection to the server, the amount of memory needed for the object model, and the speed with which the object model retrieves data.

To help you select the data retrieval object that best suits the needs of your application, the following table highlights the differences between interactivity and overhead for each object.

 Expand table

Object	Interactivity	Overhead	Retains dimensionality	Usage Information
<a href="#">CellSet</a>	Highest	Moderately high, which results in slowest retrieval of data	Yes	<a href="#">Retrieving Data Using the CellSet</a>
<a href="#">AdomdDataAdapter</a>	Moderate	Moderate	No	<a href="#">Populating a DataSet from a DataAdapter</a>
<a href="#">AdomdDataReader</a>	Moderate	Moderate	No	<a href="#">Retrieving Data Using the AdomdDataReader</a>
<a href="#">XmlReader</a>	Lowest	Lowest, which results in fastest data retrieval	Yes	<a href="#">Retrieving Data Using the XmlReader</a>

# Retrieving Data Using the AdomdDataReader

Article • 10/31/2023

When retrieving analytical data, the [AdomdDataReader](#) object provides a good balance between overhead and interactivity. The [AdomdDataReader](#) object retrieves a read-only, forward-only, flattened stream of data from an analytical data source. This unbuffered stream of data enables procedural logic to efficiently process results from an analytical data source sequentially. This makes the [AdomdDataReader](#) a good choice when retrieving large amounts of data for display purposes because the data is not cached in memory.

The [AdomdDataReader](#) can also increase application performance by retrieving data as soon as it is available, instead of waiting for the complete results of the query to be returned. The [AdomdDataReader](#) also reduces system overhead because, by default, this reader stores only one row at a time in memory.

The tradeoff for optimized performance is that the [AdomdDataReader](#) object provides less information about retrieved data than other data retrieval methods. The [AdomdDataReader](#) object does not support a large object model for representing data or metadata, nor does this object model allow for more complex analytical features like cell writeback. However, the [AdomdDataReader](#) object does provide a set of strongly typed methods for retrieving cellset data and a method for retrieving cellset metadata in a tabular format. Additionally, [AdomdDataReader](#) implements the [IDbDataReader](#) interface to support data binding and for retrieving data using the [SelectCommand](#) method, from the [System.Data](#) namespace of the Microsoft .NET Framework Class Library.

## Retrieving Data from the AdomdDataReader

To use the [AdomdDataReader](#) object to retrieve data, you follow these steps:

1. Create a new instance of the object.

To create a new instance of the [AdomdDataReader](#) class, you call the [Execute](#) or [ExecuteReader](#) method of the [AdomdCommand](#) object.

2. Retrieve data.

As the command runs the query, ADOMD.NET returns the results in the [Resultset](#) format, a tabular format as described in the XML for Analysis specification, to

flatten the data for the [AdomdDataReader](#) object. A tabular format is unusual when querying analytical data considering the variable dimensionality in such data.

ADOMD.NET stores these tabular results in the network buffer on the client until you request them by using one of the following methods:

- Call the [Read](#) method of the [AdomdDataReader](#) object.

The [Read](#) method obtains a row from the query results. You can then pass the name, or the ordinal reference, of the column to the [Item](#) property to access each column of the returned row. For example, the first column in the current row is named, `ColumnName`. Then, either `reader[0].ToString()` or `reader["ColumnName"].ToString()` will return the contents of the first column in the current row.

- Call one of the typed accessor methods.

The [AdomdDataReader](#) provides a series of typed accessor methods—methods that let you access column values in their native data types. When you know the underlying data type of a column value, a typed accessor method reduces the amount of type conversion required when retrieving the column value, and thereby, provides the highest performance.

Some of the typed accessor methods that are available include [GetDateTime](#), [GetDouble](#), and [GetInt32](#). For a complete list of typed accessor methods, see [AdomdDataReader](#).

### 3. Close the reader.

You should always call the [Close](#) method when you have finished using the [AdomdDataReader](#) object. While an instance of an [AdomdDataReader](#) object is open, the [AdomdConnection](#) is being used exclusively by that [AdomdDataReader](#). You will not be able to run any commands on the instance of the [AdomdConnection](#), including creating another [AdomdDataReader](#) or [System.Xml.XmlReader](#), until you close the original [AdomdDataReader](#).

## Example of Retrieving Data from the AdomdDataReader

The following code example iterates through a [AdomdDataReader](#) object, and returns the first two values, as strings, from each row.

VB

```
If Reader.HasRows Then
 Do While objReader.Read()
 Console.WriteLine(vbTab & "{0}" & vbTab & "{1}", _
 objReader.GetString(0), objReader.GetString(1))
 Loop
Else
 Console.WriteLine("No rows returned.")
End If

objReader.Close()
```

C#

```
if (objReader.HasRows)
 while (objReader.Read())
 Console.WriteLine("\t{0}\t{1}", _
 objReader.GetString(0), objReader.GetString(1));
else
 Console.WriteLine("No rows returned.");

objReader.Close();
```

## Retrieving Metadata from the AdomdDataReader

While an instance of an [AdomdDataReader](#) object is open, you can retrieve schema information, or metadata, about the current recordset using the [GetSchemaTable](#) method. [GetSchemaTable](#) returns a [DataTable](#) object that is populated with the schema information for the current recordset. The [DataTable](#) will contain one row for each column of the recordset. Each column of the schema table row maps to a property of the column returned in the cellset, where [ColumnName](#) is the name of the property and the value of the column is the value of the property.

## Example of Retrieving Metadata from the AdomdDataReader

The following code example writes out the schema information for an [AdomdDataReader](#) object.

VB

```
Dim schemaTable As DataTable = objReader.GetSchemaTable()

Dim objRow As DataRow
```

```
Dim objColumn As DataColumn

For Each objRow In schemaTable.Rows
 For Each objColumn In schemaTable.Columns
 Console.WriteLine(objColumn.ColumnName & " = " &
objRow(objColumn).ToString())
 Next
 Console.WriteLine()
Next
DataTable schemaTable = objReader.GetSchemaTable();
```

C#

```
foreach (DataRow objRow in schemaTable.Rows)
{
 foreach (DataColumn objColumn in schemaTable.Columns)
 Console.WriteLine(objColumn.ColumnName + " = " + objRow[objColumn]);
 Console.WriteLine();
}
```

## Retrieving Multiple Result Sets

Data mining supports the concept of nested tables, which ADOMD.NET exposes as nested rowsets. To retrieve the nested rowset associated with each row, you call the [GetDataReader](#) method.

# Retrieving Data Using the CellSet

Article • 10/31/2023

When retrieving analytical data, the [CellSet](#) object provides the most interactivity and flexibility. The [CellSet](#) object is an in-memory cache of hierarchical data and metadata that retains the original dimensionality of the data. The [CellSet](#) object can also be traversed in either a connected or disconnected state. Because of this disconnected ability, the [CellSet](#) object can be used to view data and metadata in any order and provides the most comprehensive object model for data retrieval. This disconnected capability also causes the [CellSet](#) object to have the most overhead, and to be the slowest ADOMD.NET data retrieval object model to populate.

## Retrieving Data in a Connected State

To use the [CellSet](#) object to retrieve data, you follow these steps:

1. **Create a new instance of the object.**

To create a new instance of the [CellSet](#) object, you call the [Execute](#) or [ExecuteCellSet](#) method of the [AdomdCommand](#) object.

2. **Identify metadata.**

Besides retrieving data, ADOMD.NET also retrieves metadata for the cellset. As soon as the command has run the query and returned a [CellSet](#), you can retrieve the metadata through various objects. This metadata is needed for client applications to display and interact with cellset data. For example, many client applications provide functionality for drilling down on, or hierarchically displaying the child positions of, a specified position in a cellset.

In ADOMD.NET, the [Axes](#) and [FilterAxis](#) properties of the [CellSet](#) object represent the metadata of the query and slicer axes, respectively, in the returned cellset. Both properties return references to [Axis](#) objects, which in turn contain the positions represented on each axis.

Each [Axis](#) object contains a collection of [Position](#) objects that represent the set of tuples available for that axis. Each [Position](#) object represents a single tuple that contains one or more members, represented by a collection of [Member](#) objects.

3. **Retrieve data from the cellset collection.**

Besides retrieving metadata, ADO.NET also retrieves data for the cellset. As soon as the command has run the query and returned a [CellSet](#), you can retrieve the data by using the [Cells](#) collection of the [CellSet](#). This collection contains the values that are calculated for the intersection of all axes in the query. Therefore, there are several indexers for accessing each intersection, or cell. For a list of indexers, see [Item\[\]](#).

## Example of Retrieving Data in a Connected State

The following example makes a connection to the local server, and then runs a command on the connection. The example parses the results by using the [CellSet](#) object model: the captions (metadata) for the columns are retrieved from the first axis, and the captions (metadata) for each row are retrieved from the second axis, and the intersecting data is retrieved by using the [Cells](#) collection.

cs

```
string ReturnCommandUsingCellSet()
{
 //Create a new string builder to store the results
 System.Text.StringBuilder result = new System.Text.StringBuilder();

 //Connect to the local server
 using (AdomdConnection conn = new AdomdConnection("Data
Source=localhost;"))
 {
 conn.Open();

 //Create a command, using this connection
 AdomdCommand cmd = conn.CreateCommand();
 cmd.CommandText = @"
 WITH MEMBER [Measures].[FreightCostPerOrder] AS
 [Measures].[Reseller Freight Cost]/[Measures].
[Reseller Order Quantity],
 FORMAT_STRING = 'Currency'
 SELECT
 [Geography].[Geography].[Country].&[United
States].Children ON ROWS,
 [Date].[Calendar].[Calendar Year] ON COLUMNS
 FROM [Adventure Works]
 WHERE [Measures].[FreightCostPerOrder]";

 //Execute the query, returning a cellset
 CellSet cs = cmd.ExecuteCellSet();

 //Output the column captions from the first axis
 //Note that this procedure assumes a single member exists per
column.
 result.Append("\t");
 }
}
```

```

 TupleCollection tuplesOnColumns = cs.Axes[0].Set.Tuples;
 foreach (Tuple column in tuplesOnColumns)
 {
 result.Append(column.Members[0].Caption + "\t");
 }
 result.AppendLine();

 //Output the row captions from the second axis and cell data
 //Note that this procedure assumes a two-dimensional cellset
 TupleCollection tuplesOnRows = cs.Axes[1].Set.Tuples;
 for (int row = 0; row < tuplesOnRows.Count; row++)
 {
 result.Append(tuplesOnRows[row].Members[0].Caption + "\t");
 for (int col = 0; col < tuplesOnColumns.Count; col++)
 {
 result.Append(cs.Cells[col, row].FormattedValue + "\t");
 }
 result.AppendLine();
 }
 conn.Close();

 return result.ToString();
 } // using connection
}

```

## Retrieving Data in a Disconnected State

By loading XML returned from a previous query, you can use the [CellSet](#) object to provide a comprehensive method of browsing analytical data without requiring an active connection.

### Note

Not all properties of the objects that are available from the [CellSet](#) object are available while in a disconnected state. For more information, see [LoadXml](#).

## Example of Retrieving Data in a Disconnected State

The following example is similar to the metadata and data example shown earlier in this topic. However, the command in the following example runs with a call to [ExecuteXmlReader](#), and the result is returned as a [System.Xml.XmlReader](#). The example then populates the [CellSet](#) object by using this [System.Xml.XmlReader](#) with the [LoadXml](#) method. Although this example loads the [System.Xml.XmlReader](#) immediately, you could cache the XML that is contained by the reader to a hard disk or transport that data to a different application through any means before loading the data into a cellset.

CS

```
string DemonstrateDisconnectedCellset()
{
 //Create a new string builder to store the results
 System.Text.StringBuilder result = new System.Text.StringBuilder();

 //Connect to the local server
 using (AdomdConnection conn = new AdomdConnection("Data
Source=localhost;"))
 {
 conn.Open();

 //Create a command, using this connection
 AdomdCommand cmd = conn.CreateCommand();
 cmd.CommandText = @"
 WITH MEMBER [Measures].[FreightCostPerOrder] AS
 [Measures].[Reseller Freight Cost]/[Measures].
[Reseller Order Quantity],
 FORMAT_STRING = 'Currency'
 SELECT
 [Geography].[Geography].[Country].&[United
States].Children ON ROWS,
 [Date].[Calendar].[Calendar Year] ON COLUMNS
 FROM [Adventure Works]
 WHERE [Measures].[FreightCostPerOrder]";

 //Execute the query, returning an XmlReader
 System.Xml.XmlReader x = cmd.ExecuteXmlReader();

 //At this point, the XmlReader could be stored on disk,
 //transmitted, modified, cached, or otherwise manipulated

 //Load the CellSet with the specified XML
 CellSet cs = CellSet.LoadXml(x);

 //Now that the XmlReader has finished being read
 //we can close it and the connection, while the
 //CellSet can continue being used.
 x.Close();
 conn.Close();

 //Output the column captions from the first axis
 //Note that this procedure assumes a single member exists per
column.
 result.Append("\t");
 TupleCollection tuplesOnColumns = cs.Axes[0].Set.Tuples;
 foreach (Tuple column in tuplesOnColumns)
 {
 result.Append(column.Members[0].Caption + "\t");
 }
 result.AppendLine();
 }
}
```

```
//Output the row captions from the second axis and cell data
//Note that this procedure assumes a two-dimensional cellset
TupleCollection tuplesOnRows = cs.Axes[1].Set.Tuples;
for (int row = 0; row < tuplesOnRows.Count; row++)
{
 result.Append(tuplesOnRows[row].Members[0].Caption + "\t");
 for (int col = 0; col < tuplesOnColumns.Count; col++)
 {
 result.Append(cs.Cells[col, row].FormattedValue + "\t");
 }
 result.AppendLine();
}

return result.ToString();
} // using connection
}
```

# Retrieving Data Using the XmlReader

Article • 10/31/2023

The **XmlReader** class, part of the **System.Xml** namespace for the Microsoft .NET Framework Class Library, is similar to the **AdomdDataReader** class in that the **XmlReader** class also provides fast, non-cached, forward-only access to data. If there is no need for an in-memory, analytical view of the data using the **CellSet** object, the **XmlReader** object is perfect for retrieving XML data, especially for large quantities of data. Because **XmlReader** streams data, **XmlReader** does not have to retrieve and cache all the data before exposing the data to the caller, as would be the case if a **CellSet** object were used to convert the XML for Analysis response into an analytical object model representation.

The **XmlReader** class provides direct access to the XML for Analysis response received by ADOMD.NET when the **ExecuteXmlReader** method of the **AdomdCommand** object is called. Because the retrieved data is raw XML, you must parse the data and metadata manually. As soon as the data has been retrieved, the **XmlReader** object should be closed.

## Retrieving Data and Metadata

To use the **XmlReader** class to retrieve data, you follow these steps:

1. Create a new instance of the object.

To create a new instance of the **XmlReader** class, you call the **Execute** or **ExecuteXmlReader** method of the **AdomdCommand** object.

2. Retrieve data.

After the command runs the query and returns an **XmlReader**, you must parse the data and metadata. The XML data and metadata is presented in the native format used by the XML for Analysis provider. For most XML for Analysis providers, the native format is the **MDDDataSet** format. The **MDDDataSet** format provides both data and metadata for cellsets in a well-structured format. For more information about the **MDDDataSet** format, see the XML for Analysis specification.

3. Close the reader.

You should always call the **Close** method when you have finished using the **XmlReader** object. While an **XmlReader** is open, that **XmlReader** has exclusive use of the **AdomdConnection** object that was used to run the command. You will not be able to run any commands using that

<`xref:Microsoft.AnalysisServices.AdomdClient.AdomdConnection`>, including creating another **XmlReader** or **AdomdDataReader**, until you close the original **XmlReader**.

## Example of Retrieving Data from the XmlReader

The following example runs a command and retrieves the data as an **XmlReader**, outputting the contents of the file to the console.

cs

```
void OutputDataWithXML()
{
 //Open a connection to the local server.
 AdomdConnection conn = new AdomdConnection("Data
Source=localhost");
 conn.Open();

 //Create a command to retrieve the data.
 AdomdCommand cmd = new AdomdCommand(@"WITH MEMBER [Measures].
[FreightCostPerOrder] AS
[Measures].[Reseller Freight Cost]/[Measures].[Reseller Order Quantity],
FORMAT_STRING = 'Currency'

SELECT [Geography].[Geography].[Country].&[United States].Children ON ROWS,
[Date].[Calendar].[Calendar Year] ON COLUMNS
FROM [Adventure Works]
WHERE [Measures].[FreightCostPerOrder]", conn);

 //Execute the command, retrieving an XmlReader.
 System.Xml.XmlReader reader = cmd.ExecuteXmlReader();

 //Do something with the reader: Parse data, Parse metadata,
 // Save for later loading into
CellSet, etc.
 Console.WriteLine(reader.ReadOuterXml());

 //Close the reader, then the connection
 reader.Close();
 conn.Close();

 //Await user input.
 Console.ReadLine();
}
```

# Retrieving Metadata - Working with ADOMD.NET Object Model

Article • 10/31/2023

ADOMD.NET provides an object model for viewing the cubes and subordinate objects contained by an analytical data source. However, not all metadata for a given analytical data source is available through the object model. The object model provides access to only the information that is most useful for a client application to display in order to allow a user to interactively construct commands. Because of the reduced complexity of the metadata to present, the ADOMD.NET object model is easier to use.

In the ADOMD.NET object model, the [AdomdConnection](#) object provides access to information on the online analytical processing (OLAP) cubes and mining models defined on an analytical data source, and related objects such as dimensions, named sets, and mining algorithms.

## Retrieving OLAP Metadata

Each [AdomdConnection](#) object has a collection of [CubeDef](#) objects that represent the cubes available to the user or application. The [CubeDef](#) object exposes information about the cube, as well as various objects related to the cube, such as dimensions, key performance indicators, measures, named sets, and so on.

Whenever possible, you should use the [CubeDef](#) object to represent metadata in client applications designed to support multiple OLAP servers, or for general metadata display and access purposes.

### Note

For provider specific metadata, or for detailed metadata display and access, use schema rowsets to retrieve metadata. For more information, see [Working with Schema Rowsets in ADOMD.NET](#).

The following example uses the [CubeDef](#) object to retrieve the visible cubes and their dimensions from the local server:

```
cs

private string RetrieveCubesAndDimensions()
{
```

```

System.Text.StringBuilder result = new System.Text.StringBuilder();

//Connect to the local server
using (AdomdConnection conn = new AdomdConnection("Data
Source=localhost;"))
{
 conn.Open();

 //Loop through every cube
 foreach (CubeDef cube in conn.Cubes)
 {
 //Skip hidden cubes.
 if (cube.Name.StartsWith("$"))
 continue;

 //Write the cube name
 result.AppendLine(cube.Name);

 //Write out all dimensions, indented by a tab.
 foreach (Dimension dim in cube.Dimensions)
 {
 result.Append("\t");
 result.AppendLine(dim.Name);
 }
 }

 //Close the connection
 conn.Close();
}

//Return the results
return result.ToString();
}

```

## Retrieving Data Mining Metadata

Each [AdomdConnection](#) object has several collections that provide information about the data mining capabilities of the data source:

- The [MiningModelCollection](#) contains a list of every mining model in the data source.
- The [MiningServiceCollection](#) provides information about the available mining algorithms.
- The [MiningStructureCollection](#) exposes information about the mining structures on the server.

To determine how to query against a mining model on the server, iterate through the `Microsoft.AnalysisServices.AdomdServer.MiningModel.Columns` collection. Each

[MiningModelColumn](#) object exposes the following characteristics:

- Whether the object is an input column ([IsInput](#)).
  - Whether the object is a prediction column ([IsPredictable](#)).
  - The values associated with a discrete column ([Values](#))
  - The type of data in the column ([Type](#)).
-

# Retrieving Metadata - Working with Schema Rowsets

Article • 10/31/2023

When you need more metadata than is available in the ADOMD.NET object model, ADOMD.NET provides the capability to retrieve the full range of XML for Analysis (XMLA), OLE DB, OLE DB for OLAP, and OLE DB for Data Mining schema rowsets:

## XML for Analysis metadata

The XML for Analysis schema rowsets provide a method for retrieving low-level information about the server. Information available includes the data sources available on the server, the keywords reserved by the provider, the literals supported by the provider, and more. You can even use an XML for Analysis schema rowset to discover all schema rowsets supported by the provider.

## OLE DB metadata

The OLE DB schema rowsets provide an industry-standard method for retrieving information from a variety of providers.

## OLAP metadata

Schema information provided for an analytical data source includes databases or catalogs available from the analytical data source, cubes and mining models in a database, roles that exist for cubes at the data source, and more.

## Data Mining metadata

In addition to OLAP metadata, data mining metadata can be retrieved using schema rowsets. The available rowsets expose information on the available data mining models in the database, the available mining algorithms, the parameters that the algorithm require, mining structures, and more.

For each of these various schema rowsets, you retrieve metadata from the rowset by passing either a GUID or XMLA name with the [GetSchemaDataSet](#) method of the [AdomdConnection](#) object.

## Retrieving Metadata by Passing GUIDS

The [AdomdSchemaGuid](#) class contains a list of fields that represent the schema rowsets most commonly supported by providers and analytical data sources. To retrieve both general and provider-specific metadata from a provider or analytical data source, you

use the GUIDs contained within the [AdomdSchemaGuid](#) object with the either of the following methods:

- [GetSchemaDataSet](#)
- [GetSchemaDataSet](#)

#### Note

The ADOMD.NET data provider exposes schema information through functionality made available by your specific provider and analytical data source. Each provider and data source may provide different metadata.

## Retrieving Metadata by Passing XMLA Names

The following methods take as arguments the XMLA schema name that identifies which schema information to return, and an array of restrictions on those returned columns:

- [GetSchemaDataSet](#)
- [GetSchemaDataSet](#)
- [GetSchemaDataSet](#)
- [GetSchemaDataSet](#)

Each of these methods returns an instance of a **DataSet** object that is populated with the schema information. The **DataSet** object is from the **System.Data** namespace of the Microsoft .NET Framework Class Library.

## Example

In the following example, the GetActions function takes a connection, the cube name, a coordinate, and a coordinate type, retrieves an MDSHEMA\_ACTIONS Rowset, and returns the actions available on the selected coordinate.

cs

```
//The following function can be called with the following data:
//ae.GetActions(conn, "Adventure Works","[Geography].[City]",6);

//This would return a DataSet containing the actions available for cells
//in the Adventure Works cube on [Geography].[City].
private System.Data.DataSet GetActions(AdomdConnection Connection, string
```

```
Cube, string Coordinate, int CoordinateType)
{
 //Create a restriction collection to restrict the schema information to
 be returned.
 AdomdRestrictionCollection restrictions= new
 AdomdRestrictionCollection();
 restrictions.Add("CUBE_NAME", Cube);
 restrictions.Add("COORDINATE", Coordinate);
 restrictions.Add("COORDINATE_TYPE", CoordinateType); //6 = Cell
 coordinate

 //Open and return a schema rowset, given the correct restrictions
 return Connection.GetSchemaDataSet("MDSHEMA_ACTIONS", restrictions);
}
```

# Retrieving Metadata from an Analytical Data Source

Article • 10/31/2023

Metadata is important to applications that retrieve and work with analytical data. When retrieving data from a relational data source, the dimensionality of such data is predictable, even with nested datasets. Result sets from a relational database are typically two-dimensional or scalar in structure. However, data retrieved from analytical data sources can be of variable dimensionality, organized along potentially deep hierarchies.

To handle the complexity of metadata retrieval from analytical data sources, ADOMD.NET provides two forms of metadata retrieval:

## The Object Model

The ADOMD.NET object model is generally easier to use than schema rowsets. For most scenarios, you can access the metadata of various database objects just by using the object model. ADOMD.NET exposes the object model through the [AdomdConnection](#).

For more information: [Working with the ADOMD.NET Object Model](#)

## Schema Rowsets

A complete, but more difficult approach to retrieving metadata is through using schema rowsets. A schema rowset is an OLE DB rowset that encapsulates the description for all objects of a particular type in the database. Schema information in an analytical data source includes databases or catalogs available from the data source, cubes and mining models in a database, roles that exist for cubes at the data source, and so on. This metadata can be retrieved by using the [GetSchemaDataSet](#) method, passing in either a GUID or an XML for Analysis (XMLA) name.

For more information: [Working with Schema Rowsets in ADOMD.NET](#)

Each of these metadata retrieval methods access different types of metadata. The following table describes the different metadata available for each method, and the methods used to access it.

# ADOMD.NET Server Functionality

Article • 10/31/2023

All ADOMD.NET server objects provide read-only access to the data and metadata on the server. To retrieve data and metadata, you use the ADOMD.NET server object model as the server object model does not support schema rowsets.

With ADOMD.NET server objects, you can create a user defined function (UDF) or a stored procedure for Microsoft SQL Server Analysis Services. These in-process methods are called through query statements created in languages such as Multidimensional Expressions (MDX), Data Mining Extensions (DMX), or SQL. These in-process methods also provide added functionality without the latencies associated with network communications.

## ⓘ Note

The `Microsoft.AnalysisServices.AdomdServer.AdomdCommand` object only supports DMX.

## What is a UDF?

A *UDF* is a method that has the following characteristics:

- You can call the UDF in the context of a query.
- The UDF can take any number of parameters.
- The UDF can return various types of data.

The following example uses the fictional UDF, `FinalSalesNumber`:

SQL

```
SELECT SalesPerson.Name ON ROWS,
 FinalSalesNumber() ON COLUMNS
 FROM SalesModel
```

## What is a Stored Procedure?

A *stored procedure* is a method that has the following characteristics:

- You call a stored procedure on its own with the MDX `CALL` statement.
- A stored procedure can take any number of parameters.
- A stored procedure can return a dataset, an `IDataReader`, or an empty result.

The following example uses the fictional stored procedure, `FinalSalesNumbers`:

SQL

```
CALL FinalSalesNumbers()
```

# ADOMD.NET Server Object Architecture

Article • 10/31/2023

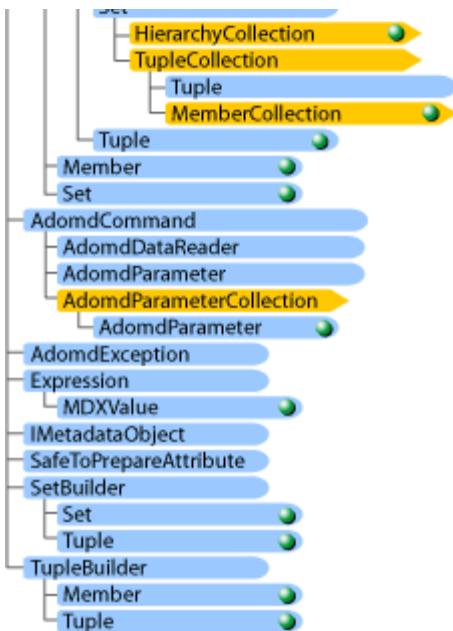

The ADOMD.NET server objects are helper objects that can be used to create user defined functions (UDFs) or stored procedures in Microsoft SQL Server Analysis Services.

## Note

To use the **Microsoft.AnalysisServices.AdomdServer** namespace (and these objects), a reference to the msmsgdsrv.dll must be added to UDF project or stored procedure.

● denotes objects expanded elsewhere in the diagram

## ADOMD.NET Object Model

Interaction with the ADOMD.NET object hierarchy typically starts with one or more of the objects in the topmost layer, as described in the following table.

[Expand table](#)

To	Use this object
Evaluate Multidimensional Expressions (MDX) expressions	<code>Microsoft.AnalysisServices.AdomdServer.Expression</code> The <code>Microsoft.AnalysisServices.AdomdServer.Expression</code> object provides a way to run an MDX expression and evaluate that expression under a specified tuple.
Provide support for executing MDX functions without constructing the full MDX statement	<code>Microsoft.AnalysisServices.AdomdServer.MDX</code> The <code>Microsoft.AnalysisServices.AdomdServer.MDX</code> object is convenient for calling predefined MDX functions without using the <code>Microsoft.AnalysisServices.AdomdServer.Expression</code> object. Additional functions for the <code>Microsoft.AnalysisServices.AdomdServer.MDX</code> object should be available in future releases.
Represent the current execution context for the UDF	<code>Microsoft.AnalysisServices.AdomdServer.Context</code> The <code>Microsoft.AnalysisServices.AdomdServer.Context</code> object exposes information such as the current cube or mining model and various metadata collections. One key use of the <code>Microsoft.AnalysisServices.AdomdServer.Context</code> object is the <code>Microsoft.AnalysisServices.AdomdServer.Hierarchy.CurrentMember</code> property of the <code>Microsoft.AnalysisServices.AdomdServer.Hierarchy</code> object. This key usage enables the author of the UDF or stored procedure to make decisions based on what member from a certain dimension the query is on.
Create sets and tuples	<code>Microsoft.AnalysisServices.AdomdServer.SetBuilder</code> , <code>Microsoft.AnalysisServices.AdomdServer.TupleBuilder</code> The <code>Microsoft.AnalysisServices.AdomdServer.SetBuilder</code> provides a way to

To	Use this object
	<p>create immutable sets, while the Microsoft.AnalysisServices.AdomdServer.TupleBuilder provides a way to create immutable tuples.</p>
Support implicit conversion and casting among the six basic types of the MDX language	<p>Microsoft.AnalysisServices.AdomdServer.MDXValue The Microsoft.AnalysisServices.AdomdServer.MDXValue object provides implicit conversion and casting among the following types:</p> <p>Microsoft.AnalysisServices.AdomdServer.Hierarchy</p> <p>Microsoft.AnalysisServices.AdomdServer.Level</p> <p>Microsoft.AnalysisServices.AdomdServer.Member</p> <p>Microsoft.AnalysisServices.AdomdServer.Tuple</p> <p>Microsoft.AnalysisServices.AdomdServer.Set</p> <p>Scalar, or value types</p>

# ADOMD.NET Server Programming

Article • 10/31/2023

The ADOMD.NET server components of ADOMD.NET reside within the **Microsoft.AnalysisServices.AdomdServer** namespace (in msmsgdsrv.dll). You use these server components to create custom Multidimensional Expressions (MDX) functions and stored procedures that are run on an instance of Microsoft SQL Server Analysis Services. The server objects provide the capabilities for querying cubes and mining models, and for evaluating expressions in a given context. The benefits for creating custom functions and stored procedures include fast execution, centralized deployment, and improved maintainability.

The topics in the following table will help you develop ADOMD.NET server applications.

  [Expand table](#)

Topic	Description
<a href="#">ADOMD.NET Server Functionality</a>	Describes the uses for ADOMD.NET server objects.
<a href="#">ADOMD.NET Server Object Architecture</a>	Describes the object architecture for ADOMD.NET server objects.
<a href="#">User Defined Functions and Stored Procedures</a>	Walks you through the process of creating a user defined function or stored Procedure.

# User Defined Functions and Stored Procedures

Article • 10/31/2023

With ADOMD.NET server objects, you can create user defined function (UDF) or stored procedures for Microsoft SQL Server Analysis Services that interact with metadata and data from the server. These in-process methods are called through Multidimensional Expressions (MDX) or Data Mining Extensions (DMX) statements to provide added functionality without the latencies associated with network communications.

## UDF Examples

A UDF is a method that can be called in the context of an MDX or DMX statement, can take any number of parameters, and can return any type of data.

A UDF created using MDX is similar to one created for DMX. The main difference is that certain properties of the `Microsoft.AnalysisServices.AdomdServer.Context` object, such as the `Microsoft.AnalysisServices.AdomdServer.Context.CurrentCube` and `Microsoft.AnalysisServices.AdomdServer.Context.CurrentMiningModel` properties, are available only for one scripting language or the other.

The following examples show how to use a UDF to return a node description, filter tuples, and apply a filter to a tuple.

### Returning a Node Description

The following example creates a UDF that returns the node description for a specified node. The UDF uses the current context in which it is being run, and uses a DMX FROM clause to retrieve the node from the current mining model.

SQL

```
public string GetNodeDescription(string nodeUniqueName)
{
 return
 Context.CurrentMiningModel.GetNodeFromUniqueName(nodeUniqueName).Description
 ;
}
```

Once deployed, the previous UDF example can be called by the following DMX expression, which retrieves the most-likely prediction node. The description contains

information that describes the conditions that make up the prediction node.

SQL

```
select Cluster(), SampleAssembly.GetNodeDescription(
PredictNodeId(Cluster())) FROM [Customer Clusters]
```

## Returning Tuples

The following example takes a set and a return count, and randomly retrieves tuples from the set, returning a final subset:

SQL

```
public Set RandomSample(Set set, int returnCount)
{
 //Return the original set if there are fewer tuples
 //in the set than the number requested.
 if (set.Tuples.Count <= returnCount)
 return set;

 System.Random r = new System.Random();
 SetBuilder returnSet = new SetBuilder();

 //Retrieve random tuples until the return set is filled.
 int i = set.Tuples.Count;
 foreach (Tuple t in set.Tuples)
 {
 if (r.Next(i) < returnCount)
 {
 returnCount--;
 returnSet.Add(t);
 }
 i--;
 //Stop the loop if we have enough tuples.
 if (returnCount == 0)
 break;
 }
 return returnSet.ToSet();
}
```

The previous example is called in the following MDX example. In this MDX example, five random states or provinces are retrieved from the **Adventure Works** database.

SQL

```
SELECT SampleAssembly.RandomSample([Geography].[State-Province].Members, 5)
on ROWS,
[Date].[Calendar].[Calendar Year] on COLUMNS
```

```
FROM [Adventure Works]
WHERE [Measures].[Reseller Freight Cost]
```

## Applying a Filter to a Tuple

In the following example, a UDF is defined that takes a set, and applies a filter to each tuple in the set, using the Expression object. Any tuples that conform to the filter will be added to a set that is returned.

CS

```
public static Set FilterSet(Set set, String filterExpression)
{
 Expression expr = new Expression(filterExpression);

 SetBuilder resultSetBuilder = new SetBuilder();

 foreach (Tuple tuple in set)
 {
 if ((bool)(expr.Calculate(tuple)))
 {
 resultSetBuilder.Add(tuple);
 }
 }

 return resultSetBuilder.ToSet();
}
```

The previous example is called in the following MDX example, which filters the set to cities with names beginning with 'A'.

SQL

```
Select Measures.Members on Rows,
SampleAssembly.FilterSet([Customer].[Customer Geography].[City], "
[Customer].[Customer Geography].[City].CurrentMember.Name < 'B'") on Columns
From [Adventure Works]
```

## Stored Procedure Example

In the following example, an MDX-based stored procedure uses AMO to create partitions, if needed, for Internet Sales.

CS

```

public static void CreateInternetSalesMeasureGroupPartitions()
{
 //Check the current state of the data warehouse and
 //create partitions with AMO if necessary
 #region Retrieve order date of last sales transaction

 // Open a connection to the data warehouse
 // TODO: Change the first string parameter to reflect the right
server\instance.

 SqlConnection conn = new SqlConnection(string.Format("data source=
{0};initial catalog={1};Integrated Security=SSPI", "server\\instance",
Context.CurrentDatabaseName));
 conn.Open();

 // Create a command
 SqlCommand cmd = new SqlCommand();
 cmd.Connection = conn;

 // Get the order date key of the last internet sale
 int lastInternetSaleDateKey = 0;
 cmd.CommandText = "select max(OrderDateKey) from FactInternetSales";
 lastInternetSaleDateKey = (int)cmd.ExecuteScalar();

 // Get the order date key of the last reseller sale
 int lastResellerSaleDateKey = 0;
 cmd.CommandText = "select max(OrderDateKey) from FactResellerSales";
 lastResellerSaleDateKey = (int)cmd.ExecuteScalar();
 #endregion

 #region Create partitions

 // Connect to the calling session
 Server svr = new Server();
 svr.Connect("*");

 // Get the Adventure Works cube
 Database db = svr.Databases.GetByName(Context.CurrentDatabaseName);
 Cube cube = db.Cubes[0];

 MeasureGroup mg;
 int maxOrderDateKey;

 mg = cube.MeasureGroups.GetByName("Internet Sales");
 maxOrderDateKey = 0;
 foreach (Partition part in mg.Partitions)
 {
 maxOrderDateKey = Math.Max(maxOrderDateKey, Convert.ToInt32(
 part.Annotations.Find("LastOrderDateKey").Value.Value,
 System.Globalization.CultureInfo.InvariantCulture));
 }

 if (maxOrderDateKey < lastInternetSaleDateKey)
 {
 Partition part = mg.Partitions.Add("Internet_Sales_"

```

```
 + lastInternetSaleDateKey);
part.StorageMode = StorageMode.Molap;
part.Source = new QueryBinding(db.DataSources[0].ID,
 "SELECT * FROM [dbo].[FactInternetSales] WHERE OrderDateKey > ''"
 + maxOrderDateKey + "' and OrderDateKey <= '" +
lastInternetSaleDateKey + "'");
part.Annotations.Add("LastOrderDateKey",
Convert.ToString(lastInternetSaleDateKey,
 System.Globalization.CultureInfo.InvariantCulture));
part.Update();
part.Process();
}

svr.Disconnect();

#endregion
}
```

# XML for Analysis (XMLA) Reference

Article • 12/09/2022

Applies to:  SQL Server Analysis Services  Azure Analysis Services   
Fabric/Power BI Premium

Azure Analysis Services, SQL Server Analysis Services, and Power BI Premium use XML for Analysis (XMLA) protocol for communications between client applications and an Analysis Services instance. At their most basic level, other client libraries such as ADOMD.NET and AMO construct requests and decode responses in XMLA, serving as an intermediary to an Analysis Services instance, which uses XMLA exclusively.

To support the discovery and manipulation of data in both tabular and multidimensional modes, the XMLA specification defines two generally accessible methods, [Discover](#) and [Execute](#), and a collection of XML elements and data types. Because XML allows for a loosely coupled client and server architecture, both methods handle incoming and outgoing information in XML format.

Analysis Services is compliant with the XMLA 1.1. specification, but also extends it to include data definition and manipulation capability, implemented as annotations on the [Discover](#) and [Execute](#) methods. The extended XML syntaxes are Tabular Model Scripting Language (TMSL) and Analysis Services Scripting Language (ASSL).

[Tabular Model Scripting Language](#) (TMSL) is the command and object model definition syntax for tabular model databases at compatibility level 1200 and higher. TMSL communicates with Analysis Services through the XMLA protocol, where the `XMLA.Execute` method accepts both JSON-based statement scripts in TMSL as well as the traditional XML-based scripts in [Analysis Services Scripting Language](#) (ASSL for XMLA).

ASSL is the command and object model definition syntax for multidimensional model databases and tabular model databases at compatibility level 1103 or lower. This definition builds on the XMLA specification without breaking it. Interoperability based on XMLA is ensured whether you use just XMLA, or XMLA and ASSL together.

As a developer, you can use XMLA as an interface if solution requirements specify standard protocols such as XML, SOAP, and HTTP. Developers and administrators can also use XMLA on an ad-hoc basis to retrieve information from the server or run commands.

# XML for Analysis (XMLA) Compliance

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

The XML for Analysis 1.1 specification describes an open standard that supports data access to data sources that reside on the World Wide Web. This article details the level of compliance with the XML for Analysis 1.1 specification supported by all Analysis Services platforms: Azure Analysis Services, SQL Server Analysis Services, and Power BI Premium.

## Compliant items

Analysis Services complies with all mandatory items listed in the XML for Analysis 1.1 specification. In addition, Analysis Services implements the following optional item described in the XML for Analysis 1.1 specification.

Expand table

Item	Specification	Implementation
Session support	The SOAP header elements listed in "Support for Statefulness in XML for Analysis" section of the XML for Analysis 1.1 specification.	All listed SOAP header elements are supported by Analysis Services, as described within the specification.

## Extensions

Analysis Services also extends the XML for Analysis 1.1 specification to support the following additional features and capabilities.

Expand table

Item	Specification	Implementation
Protocol negotiation	No information contained in the XML for Analysis 1.1 specification	ProtocolCapabilities header element added by Analysis Services to support negotiation of protocol capabilities.
XML for Analysis (XMLA) commands supported	The following commands are supported by the XML	The following commands are supported by Analysis Services:

Item	Specification	Implementation
by the Discover method	for Analysis 1.1 specification:	<a href="#">Alter Element (XMLA)</a>
	<a href="#">Statement Element (XMLA)</a>	<a href="#">Backup Element (XMLA)</a>
		<a href="#">Batch Element (XMLA)</a>

# XML Data Types (XMLA)

Article • 12/09/2022

In addition to the standard primitive and derived types defined by the XML 1.0 recommendation, the XML for Analysis (XMLA) 1.1 specification defines additional data types to support the representation of multidimensional and tabular data.

XMLA uses the data types listed in the following table.

[ ] Expand table

Data types	Description
Boolean	The standard XML <b>boolean</b> data type.
Decimal	The standard XML <b>decimal</b> data type.
EmptyResult	A namespace on the <b>root</b> element. This namespace is returned when an XMLA command does not return a result because either the XMLA command does not normally return a result or because an error occurred on the Analysis Services instance while executing the XMLA command.
EnumString	A set of named string constants for a given enumerator.
Integer	The standard XML <b>int</b> data type.
MDDataset	Multidimensional data returned by the <i>Result</i> parameter of the <a href="#">Execute</a> method.
Resultset	A self-describing XML result set returned by the <a href="#">Execute</a> method.
Rowset	Rows from a data source, structured by an embedded XML schema, returned by the <a href="#">Discover</a> method.
String	The XML <b>string</b> data type.
UnsignedInt	The XML <b>unsignedInt</b> schema type.

For complete descriptions of the standard XML data types, see the World Wide Web Consortium (WC3) candidate recommendation.

# EmptyResult Data Type (XMLA)

Article • 12/09/2022

Defines a derived data type that represents a [root](#) element that does not return data from a [Discover](#) or [Execute](#) method call.

**Namespace** urn:schemas-microsoft-com:xml-analysis:empty

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:empty">
 <!-- All elements are inherited from Resultset -->
</root>
```

## Data type characteristics

[\[+\] Expand table](#)

Characteristic	Description
Base data types	<a href="#">Resultset</a>
Derived data types	None

## Data type relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	None
Child elements	None
Derived elements	<a href="#">root</a>

## Remarks

Some XML for Analysis (XMLA) commands are not expected to return a result, or could not return a result because of an error. XMLA commands that do not return a result return the **EmptyResult** data type, a namespace on the **root** element.

## Example

The following example represents a **root** element returned for an empty result.

XML

```
<return>
 <root xmlns="urn:schemas-microsoft-com:xml-analysis:empty"/>
</return>
```

---

# EnumString Data Type (XMLA)

Article • 12/09/2022

Defines a derived data type that represents a set of named constants for a given enumerator.

## Syntax

XML

```
<EnumString>...</EnumString>
```

## Data type characteristics

[+] Expand table

Characteristic	Description
Base data types	string
Derived data types	None

## Data type relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	None
Derived elements	None

## Remarks

XML for Analysis (XMLA) uses enumerations to limit string values to a set of verifiable settings. **EnumString** uses the standard XML **string** data type. The specific values for each of the named constants are specified with the enumerator definition. Enumerators

are defined by adding them to the DISCOVER\_ENUMERATORS schema rowset, and can be retrieved by using the [Discover](#) method with the DISCOVER\_ENUMERATORS request type.

The following table describes the enumerators supported by an instance of Analysis Services.

[+] [Expand table](#)

Enumerator	Description
ProviderType	Supports the ProviderType column in the DISCOVER_DATASOURCES schema rowset, which determines the type of data that can be returned by an Analysis Services instance.
	This enumeration also supports the XMLA property, <b>ProviderType</b> , which determines the provider types supported by an Analysis Services instance. This enumeration is also used in the DISCOVER_DATASOURCES schema rowset.
	For more information about <b>ProviderType</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .
AuthenticationMode	Supports the AuthenticationMode column in the DISCOVER_DATASOURCES schema rowset, which determines the security credentials that must be passed to access an Analysis Services instance.
PropertyAccessType	Supports the PropertyAccessType column in the DISCOVER_PROPERTIES schema rowset, which determines the type of access available to an XMLA property.
StateSupport	Supports the XMLA property, <b>StateSupport</b> , which determines the level of statefulness supported by an Analysis Services instance.
	For more information about <b>StateSupport</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .
StateActionVerb	Contains a list of verbs supported by XMLA in SOAP headers, and used to begin, identify, and end a session.
ResultsetFormat	Supports the XMLA property, <b>Format</b> , which determines the type of data returned in a <b>root</b> element.
	For more information about <b>Format</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .
ResultsetAxisFormat	Supports the XMLA property, <b>AxisFormat</b> , which determines the format of axis information returned in a <b>root</b> element that contains multidimensional data.

Enumerator	Description
	For more information about <b>AxisFormat</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .
ResultSetContents	Supports the XMLA property, <b>Content</b> , which determines whether metadata or data is returned in a <b>root</b> element.  For more information about <b>Content</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .
MDXSupportLevel	Supports the XMLA property, <b>MDXSupport</b> , which indicates the level of Multidimensional Expressions (MDX) support available on an Analysis Services instance.  For more information about <b>MDXSupport</b> , see <a href="#">Supported XMLA Properties (XMLA)</a> .

# MDDataSet Data Type (XMLA)

Article • 12/09/2022

Defines a derived data type that represents multidimensional data returned by the [Execute](#) method.

**Namespace** urn:schemas-microsoft-com:xml-analysis:mddataset

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
 <!-- The following elements extend Resultset -->
 <!-- Optional schema elements -->
 <OlapInfo>...</OlapInfo>
 <Axes>...</Axes>
 <CellData>...</CellData>
</root>
```

## Data type characteristics

[ ] Expand table

Characteristic	Description
Base data types	<a href="#">Resultset</a>
Derived data types	None

## Data type relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Axes</a> , <a href="#">CellData</a> , <a href="#">OlapInfo</a>
Derived elements	None

## Remarks

The **MDDDataSet** data type provides the OLAP-oriented rowset (or dataset) required to represent OLAP data in XML. The contents of this rowset can vary depending on the values of the **Content** and **Format** properties provided in the [Properties](#) collection of the **Execute** method. For more information about the **Content** and **Format** properties, see [Supported XMLA Properties \(XMLA\)](#).

For basic information about the OLE DB for OLAP dataset structures, refer to "MDDDataSet Data Type Mapping to OLE DB" in the XML for Analysis 1.1 specification. For a full XML Schema definition language (XSD) sample of the **MDDDataSet** data type, refer to "Appendix D: MDDDataSet Example" of the XML for Analysis 1.1 specification.

# Resultset Data Type (XMLA)

Article • 12/09/2022

Defines an abstract primitive data type that represents data returned from a [Discover](#) or [Execute](#) method call.

**Namespace** urn:schemas-microsoft-com:xml-analysis:resultset

## Syntax

XML

```
<Resultset>
 <Exception>...</Exception>
 <Messages>...</Messages>
</Resultset>
```

## Data type characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	<a href="#">MDDataSet</a> , <a href="#">olapxmla_EmptyResult</a> , <a href="#">Rowset</a>

## Data type relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Exception</a> , <a href="#">Messages</a>
Derived elements	None

## Remarks

The **Resultset** data type is a self-describing XML result set that can include both schema and data, depending on the type of information to be returned.

---

# Rowset Data Type (XMLA)

Article • 12/09/2022

Defines a derived data type that represents a [root](#) element that returns tabular data from a [Discover](#) or [Execute](#) method call.

**Namespace** urn:schemas-microsoft-com:xml-analysis:rowset

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
 <!-- The following elements extend Resultset -->
 <!-- Optional schema elements -->
 <row>...</row>
</root>
```

## Data type characteristics

[ ] Expand table

Characteristic	Description
Base data types	<a href="#">Resultset</a>
Derived data types	None

## Data type relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">row</a>
Derived elements	<a href="#">root</a>

## Remarks

XML does not allow certain characters as element and attribute names. To address this naming constraint, XML for Analysis (XMLA) supports encoding as defined by Analysis Services. For column names that contain XML name characters that are not valid according to the XML 1.0 specification, XMLA uses the corresponding hexadecimal values to encode Unicode characters that are not valid. The hexadecimal values are escaped as \_xHHHH\_, where HHHH stands for the four-digit hexadecimal UCS-2 code for the character in the most-significant bit first order. For example, XMLA encodes the name, "Order Details," as Order\_x0020\_Details, replacing the space character with the corresponding hexadecimal code.

Encoding can make Extensible Style Language (XSL) transformations difficult. To support a quick lookup of the actual, unencoded column names, add the `sql:field` attribute to the XML rowset schema for each column, as shown in the following example:

XML

```
<xsd:element name="Order_x0020_Details" type="string" sql:field="Order
Details" />
```

### ⓘ Note

The `sql:field` attribute is in the `"urn:schemas-microsoft-com:xml-sql"` namespace.

## Expressing a Null Value

There are two ways to express a null value for a column within a row:

- A missing column element implies that the column is null.
- The column element may use the `xsi:nil='true'` attribute to indicate that it has a null value.

For example, a row has a single column called, `Store_Name`, and the value of that column is `NONE`. The value of the `Store_Name` column can be represented as a missing column element:Or, the value of the `Store_Name` column can be represented using the `xsi:nil='true'` attribute:

XML

```
<row>
 <Store_name xsi:nil='true' />
</row>
```

## Example

### XMLA Rowset for Flat Data

For flat data, column names that are specific to the query are defined in the schema as the element names. Also, a pair of `<row>` tags encapsulates each row.

The following example shows the XMLA rowset format for flat data.

```
XML

<return>
 <root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
 <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:sql="urn:schemas-microsoft-com:xml-sql">
 <xsd:element>
 <xsd:complexType name="row">
 <xsd:choice maxOccurs="unbounded" minOccurs="0">
 <xsd:element name="CATALOG_NAME" type="xsd:string"
 sql:field="CATALOG_NAME"></xsd:element>
 <xsd:element name="DESCRIPTION" type="xsd:string"
 sql:field="DESCRIPTION"></xsd:element>
 <xsd:element name="ROLES" type="xsd:string" sql:field="ROLES">
 </xsd:element>
 <xsd:element name="DATE_MODIFIED" type="xsd:time"
 sql:field="DATE_MODIFIED"></xsd:element>
 </xsd:choice>
 </xsd:complexType>
 </xsd:schema>
 <row>
 <CATALOG_NAME>FoodMart 2000</CATALOG_NAME>
 <DESCRIPTION></DESCRIPTION>
 <ROLES>All Users</ROLES>
 <DATE_MODIFIED>3/11/2001 6:49:36 PM</DATE_MODIFIED>
 </row>
 ...
 </root>
```

### XMLA Rowset for Hierarchical Data

Some rowsets contain hierarchical data (or nested rowsets). Rowsets returned by data mining queries are hierarchical. For hierarchical data, the structure of the rows is not changed, but the data-specific schema defines an element subtype that contains the nested data.

The following example shows the XMLA rowset format for hierarchical data. In this example, the element subtype that contains the nested data is `<NODE\_DISTRIBUTION>.

#### XML

```
<?xml version="1.0" encoding="UTF-8"?>
<root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
 <xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:sql="urn:schemas-microsoft-com:xml-sql">
 <xsd:complexType name="row">
 <xsd:choice maxOccurs="unbounded" minOccurs="0">
 <xsd:sequence maxOccurs="unbounded" minOccurs="0">

# XML Elements - Commands

Article • 12/09/2022

This reference section contains XML for Analysis (XMLA) elements that can be used within the **Command** element during an **Execute** method call.

[ ] Expand table

Element	Description
<a href="#">Alter Element (XMLA)</a>	Contains Analysis Services Scripting Language (ASSL) elements used by the <b>Execute</b> method to alter objects on an instance of Analysis Services.
<a href="#">Backup Element</a>	Backs up a Analysis Services database to a backup file.
<a href="#">Batch Element</a>	Performs one or more XML for Analysis (XMLA) commands as a batch operation, either sequentially or in parallel, on an instance of Analysis Services.
<a href="#">BeginTransaction Element</a>	Begins a transaction on the current session with an Analysis Services instance.
<a href="#">Cancel Element</a>	Cancels a currently running command on an Analysis Services instance.
<a href="#">ClearCache Element</a>	Clears the memory cache for the specified object on an Analysis Services instance.
<a href="#">CommitTransaction Element</a>	Commits a transaction on the current session with an Analysis Services instance.
<a href="#">Create Element</a>	Contains Analysis Services Scripting Language (ASSL) elements used by the <b>Execute</b> method to create objects on an Analysis Services instance.
<a href="#">Delete Element</a>	Deletes an object on an Analysis Services instance.
<a href="#">DesignAggregations Element</a>	Creates aggregations for an aggregation design on an Analysis Services instance.
<a href="#">Drop Element</a>	Deletes attribute members from a dimension.
<a href="#">Insert Element</a>	Inserts attribute members into a dimension.
<a href="#">Lock Element</a>	Locks a specified object on an Analysis Services instance.
<a href="#">MergePartitions Element</a>	Merges the data of one or more source partitions into a target partition, and then deletes the source partitions.
<a href="#">NotifyTableChange Element</a>	Notifies an Analysis Services instance that a change has occurred to tables in a specified data source.

Element	Description
Process Element	Processes objects on an Analysis Services instance.
Restore Element	Restores an Analysis Services database from a backup file.
RollbackTransaction Element	Rolls back a transaction on the current session with an Analysis Services instance.
Statement Element	Contains a query or statement to be sent using the <a href="#">Execute</a> method to an instance of Analysis Services.
Subscribe Element	Subscribes to a trace and returns a rowset containing the trace events from an Analysis Services instance.
Synchronize Element	Synchronizes an Analysis Services database with another existing database.
Unlock Element	Unlocks a specified lock on an Analysis Services instance.
Update Element	Updates attribute members in a dimension.
UpdateCells Element	Updates cells in a write-enabled cube.

---

# Alter Element (XMLA)

Article • 12/09/2022

Contains Analysis Services Scripting Language (ASSL) elements used by the [Execute](#) method to alter objects on an instance of Analysis Services.

## Syntax

XML

```
<Command>
 <Alter Scope="enum" AllowCreate="boolean" ObjectExpansion="enum">
 <Object>...</Object>
 <ObjectDefinition>...</ObjectDefinition>
 </Alter>
</Command>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">Object</a> , <a href="#">ObjectDefinition</a>

## Attributes

Attribute	Description
AllowCreate	<p>(Optional <b>Boolean</b> attribute) Indicates whether objects defined in the <b>Alter</b> command should be created if they do not already exist.</p> <p>If set to true, the objects defined in the <b>ObjectDefinition</b> element are created on the Analysis Services instance if they do not already exist. In other words, the <b>Alter</b> command is treated as a <b>Create</b> command if the objects do not already exist on the instance.</p> <p>If this attribute is omitted or set to <b>false</b>, an error occurs if the objects do not already exist.</p>
ObjectExpansion	<p>(Optional <b>Enum</b> attribute) Defines the extent of alteration to be performed by the <b>Execute</b> method.</p> <p>If set to <i>ObjectProperties</i>, the <b>ObjectDefinition</b> element should contain only the complete definition of the major object to be altered, including subordinate minor objects. Subordinate major objects of the object to be altered remain unchanged.</p> <p>Note: When using the <i>ObjectProperties</i> setting with the <b>ClrAssembly</b> data type, the <b>Data</b> element of the associated <b>ClrAssemblyFile</b> data types does not need to be specified. If not specified, the <b>ClrAssembly</b> uses existing files.</p> <p>If set to <i>ExpandFull</i>, the <b>ObjectDefinition</b> element should contain not just the definition of the object to be altered, but also the definitions of all major objects which are descendants of the object to be altered.</p> <p>Note: The <i>ExpandFull</i> setting cannot be used with the <b>Server</b> element.</p>
Scope	<p>(Optional <b>Enum</b> attribute) Defines the duration of objects defined in the <b>ObjectDefinition</b> element.</p> <p>If set to <i>Session</i>, the objects defined in the <b>ObjectDefinition</b> element exist only for the duration of the XMLA session.</p> <p>Note: When using the <i>Session</i> setting, the <b>ObjectDefinition</b> element can only contain <b>Dimension</b>, <b>Cube</b>, or <b>MiningModel</b> ASSL elements.</p> <p>If this attribute is omitted, the objects defined in the <b>ObjectDefinition</b> element are persisted on the Analysis Services instance.</p>

## Remarks

Each **Alter** command changes the definition of one major object under the parent object specified by the [ParentObject](#) element.

# Backup Element (XMLA)

Article • 12/09/2022

Backs up a Analysis Services database to a backup file.

## Syntax

XML

```
<Command>
 <Backup>
 <Object>...</Object>
 <File>...</File>
 <Security>...</Security>
 <ApplyCompression>...</ApplyCompression>
 <AllowOverwrite>...</AllowOverwrite>
 <Password>...</Password>
 <BackupRemotePartitions>...</BackupRemotePartitions>
 <Locations>...</Locations>
 </Backup>
</Command>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	Command

Relationship	Element
Child elements	<a href="#">AllowOverwrite</a> , <a href="#">ApplyCompression</a> , <a href="#">BackupRemotePartitions</a> , <a href="#">File</a> , <a href="#">Locations</a> , <a href="#">Object</a> , <a href="#">Password</a> , <a href="#">Security</a>

## Remarks

The **Backup** command backs up the Analysis Services database specified in the **Object** element to a backup file, and optionally backs up remote partitions to remote backup files. If the **Object** element refers to an object other than an Analysis Services database, an error occurs.

Which information the **Backup** command backs up depends on the storage mode used by objects in the database. The following table identifies the information that is backed up based upon the storage mode used.

[\[+\] Expand table](#)

Storage mode	Information that is backed up
Multidimensional OLAP (MOLAP)	Source data, aggregations, and metadata
Hybrid OLAP (HOLAP)	Aggregations and metadata
Relational OLAP (ROLAP)	Metadata

During a **Backup** command, a shared lock is placed on the Analysis Services database specified in the **Object** element. The shared lock releases after the **Backup** command has completed.

Multiple **Backup** commands can be run in parallel, if the commands are included in the **Parallel** collection of a **Batch** command. The **Parallel** collection enables a database to be backed up into multiple backup files at the same time.

### Important

For each backup file, the user who runs the backup command must have permission to write to the backup location specified for each file. Also, the user must have one of the following roles: a member of a server role for the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be backed up.

# Batch Element (XMLA)

Article • 12/09/2022

Performs one or more XML for Analysis (XMLA) commands as a batch operation, either sequentially or in parallel, on an instance of Analysis Services.

## Syntax

```
XML

<Command>
 <Batch Transaction="Boolean" ProcessAffectedObjects="Boolean">
 <Bindings>...</Bindings>
 <DataSource>...</DataSource>
 <DataSourceView>...</DataSourceView>
 <ErrorConfiguration>...</ErrorConfiguration>
 <Parallel>...</Parallel>
 <!-- One or more XMLA commands -->
 </Batch>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	Command

Relationship	Element
Child elements	<p><a href="#">Bindings</a>, <a href="#">DataSource</a>, <a href="#">DataSourceView</a>, <a href="#">ErrorConfiguration</a>, <a href="#">Parallel</a></p> <p>One or more of the following XMLA commands: <a href="#">Alter</a>, <a href="#">Backup</a>, <a href="#">BeginTransaction</a>, <a href="#">ClearCache</a>, <a href="#">CommitTransaction</a>, <a href="#">Create</a>, <a href="#">Delete</a>, <a href="#">DesignAggregations</a>, <a href="#">Drop</a>, <a href="#">Insert</a>, <a href="#">Lock</a>, <a href="#">MergePartitions</a>, <a href="#">NotifyTableChange</a>, <a href="#">Process</a>, <a href="#">Restore</a>, <a href="#">RollbackTransaction</a>, <a href="#">SetPasswordEncryptionKey</a>, <a href="#">Statement</a>, <a href="#">Subscribe</a>, <a href="#">Synchronize</a>, <a href="#">Unlock</a>, <a href="#">Update</a>, <a href="#">UpdateCells</a></p>

## Attributes

[\[+\] Expand table](#)

Attribute	Description
ProcessAffectedObjects	<p>(Optional <b>Boolean</b> attribute) Indicates whether all objects that require reprocessing will be processed.</p> <p>If set to <b>true</b>, the Analysis Services instance processes any objects that require reprocessing as a result of processing an object included in the <b>Batch</b> command.</p> <p>If set to <b>false</b>, the Analysis Services instance processes only those objects included in the <b>Batch</b> command.</p>
Transaction	<p>(Optional <b>Boolean</b> attribute) Indicates whether the command included in the <b>Batch</b> command are treated as a single transaction or individual transactions.</p> <p>If set to <b>true</b>, all of the commands included in the <b>Batch</b> command are considered a single transaction. If any command fails, the commands executed prior to the failed command are rolled back, and the <b>Batch</b> command stops without executing subsequent commands.</p> <p>If set to <b>false</b>, the <b>Batch</b> command attempts to execute every command, and commits the results of each command that completes successfully.</p>

## Remarks

### Warning

Command/Execute/Statement is currently not supported in a Batch operation.

# Feedback

Was this page helpful?

 Yes

 No

# BeginTransaction Element (XMLA)

Article • 12/09/2022

Begins a transaction on the current session with an instance of Analysis Services.

## Syntax

XML

```
<Command>
 <BeginTransaction />
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	None

## Remarks

The **BeginTransaction** command begins an active transaction on the current session. If an active transaction already exists, the Analysis Services instance increments the

reference count of transactions for the current session. If not, the instance will begin a new transaction and set the reference count for the current session to 1. If an active transaction is explicitly specified using the **BeginTransaction** command, all subsequent commands are executed inside the explicitly specified transaction.

When the current session is ended and the reference count for transactions is higher than zero, all active transactions are rolled back.

If there are no explicitly specified active transactions on the current session, every command issued on the current session is executed inside an implicitly defined transaction. The implicit transaction is committed if the command succeeds, or rolled back if the command fails.

# Cancel Element (XMLA)

Article • 12/09/2022

Cancels a currently running command an Analysis Services instance.

## Syntax

XML

```
<Command>
 <Cancel>
 <ConnectionID>...</ConnectionID>
 <SessionID>...</SessionID>
 <SPID>...</SPID>
 <CancelAssociated>...</CancelAssociated>
 </Cancel>
</Command>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">CancelAssociated</a> , <a href="#">ConnectionID</a> , <a href="#">SessionID</a> , <a href="#">SPID</a>

# Remarks

The **Cancel** command cancels currently executing commands within the context of a session. If the client application has not requested a session, a command cannot be canceled.

If the **Cancel** command is executed during the execution of a **Batch** command, the entire **Batch** command is canceled. If the **Batch** command was transactional, all of the commands contained by the **Batch** command are rolled back. If the **Batch** command was not transactional, only those commands contained by the **Batch** command that were executing at the time the **Cancel** command was executed are rolled back.

Commands in a non-transactional **Batch** command that had already executed would not be rolled back.

Typically, the **Cancel** command is used to cancel executing commands on the currently active session. In that case, none of the child elements for the **Cancel** command must be specified. The **Cancel** command can also be used by administrators to cancel commands executing on connections or sessions other than the currently active session. Members of a role that has Administer permissions for a given database can cancel commands for connections and sessions applicable to that database, while server administrators can cancel commands for connections and sessions for a given Analysis Services instance.

To retrieve information about current connections and sessions for an Analysis Services instance, the **Discover** method can be executed to request, respectively, the **DISCOVER\_CONNECTIONS** and **DISCOVER\_SESSIONS** schema rowsets. Members of a role that has Administer permissions for a given database can return sessions only for a given database by specifying that database in the **SESSION\_CURRENT\_DATABASE** restriction column for the **DISCOVER\_SESSIONS** schema rowset. For more information about the **Discover** method, see [Discover Method \(XMLA\)](#).

---

Was this page helpful?

 Yes

 No

# ClearCache Element (XMLA)

Article • 12/09/2022

Clears the memory cache for the specified object on a Analysis Services instance.

## Syntax

XML

```
<Command>
 <ClearCache>
 <Object>...</Object>
 </ClearCache>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">Object</a>

## Remarks

The **ClearCache** command flushes the cache for a specified database, dimension, cube, measure group, or partition on an Analysis Services instance. If an object other than a database, dimension, cube, measure group, or partition is specified in the **Object** element, an error occurs.

---

## Feedback

Was this page helpful?

# CommitTransaction Element (XMLA)

Article • 12/09/2022

Commits a transaction on the current session with a Analysis Services instance.

## Syntax

XML

```
<Command>
 <CommitTransaction />
</Command>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	None

## Remarks

The **CommitTransaction** command commits an active transaction, explicitly defined using the **BeginTransaction** element, on the current session. If an active transaction

does not already exist, an error occurs. If an active transaction already exists, the Analysis Services instance decrements the reference count of transactions for the current session. If the reference count of explicitly defined active transactions reaches zero, the Analysis Services instance commits the transaction.

---

# Create Element (XMLA)

Article • 12/09/2022

Contains Analysis Services Scripting Language (ASSL) elements used by the **Execute** method to create objects on a Analysis Services instance.

## Syntax

XML

```
<Command>
 <Create Scope="enum" AllowOverwrite="boolean">
 <ParentObject>...</ParentObject>
 <ObjectDefinition>...</ObjectDefinition>
 </Create>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">ObjectDefinition</a> , <a href="#">ParentObject</a>

## Attributes

Attribute	Description
AllowOverwrite	Optional <b>Boolean</b> attribute. If set to True, the objects defined in the <b>ObjectDefinition</b> element can overwrite existing objects on the Analysis Services instance. If this attribute is omitted or set to False, the presence of an existing object generates an error.
Scope	<p>Optional <b>Enum</b> attribute. Defines the duration of objects defined in the <b>ObjectDefinition</b> element. If this attribute is omitted, the objects defined in the <b>ObjectDefinition</b> element are persisted on the Analysis Services instance. The following value is available:</p> <p><i>Session</i>: The objects defined in the <b>ObjectDefinition</b> element exist only for the duration of the XML for Analysis (XMLA) session.  Note that when using the <i>Session</i> setting, the <b>ObjectDefinition</b> element can only contain <b>Dimension</b>, <b>Cube</b>, or <b>MiningModel</b> ASSL elements.</p>

## Remarks

Each **Create** operation creates one major object under a parent given by the **ParentObject** element. If the parent object is omitted, it is assumed to be the destination Analysis Services instance. This generates an error if the parent of a major object is not the destination instance.

## Example

The following example creates an empty database named **Test Database** on an Analysis Services instance.

XML

```

<Create
xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
 <ObjectDefinition>
 <Database xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <Name>Test Database</Name>
 <Description>A test database.</Description>
 </Database>
 </ObjectDefinition>
</Create>
```

# Feedback

# DesignAggregations Element (XMLA)

Article • 12/09/2022

Creates aggregations for an aggregation design on a Analysis Services instance.

## Syntax

XML

```
<Command>
 <DesignAggregations>
 <Object>...</Object>
 <Time>...</Time>
 <Steps>...</Steps>
 <Optimization>...</Optimization>
 <Storage>...</Storage>
 <Materialize>...</Materialize>
 <Queries>...</Queries>
 </DesignAggregations>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	Command
Child elements	Materialize, Object, Optimization, Queries, Steps, Storage, Time

# Remarks

The **DesignAggregations** command is used to generate aggregation definitions stored by an aggregation design. An aggregation design can then be used to materialize aggregations for a partition and can be reused between partitions.

# Lock Element (XMLEA)

Article • 12/09/2022

Locks a specified object on a Analysis Services instance.

## Syntax

XML

```
<Command>
 <Lock>
 <ID>...</ID>
 <Object>...</Object>
 <Mode>...</Mode>
 </Lock>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">ID</a> , <a href="#">Mode</a> , <a href="#">Object</a>

## Remarks

The **Lock** command locks an object, either for shared or exclusive use, within the context of the currently active transaction. Only database administrators or server administrators can explicitly issue a **Lock** command. A lock on an object prevents transactions from committing until the lock is removed. Analysis Services supports two types of locks, shared locks and exclusive locks.

Analysis Services allows only databases to be locked. The **Object** element must contain an object reference to an Analysis Services database. If the **Object** element is not specified or if the **Object** element refers to an object other than a database, an error occurs.

Other commands implicitly issue a **Lock** command on an Analysis Services database. Any operation that reads data or metadata from a database, such as any **Discover** method or an **Execute** method running a **Statement** command, implicitly issues a shared lock on the database. Any transaction that commits changes in data or metadata to an object on an Analysis Services database, such as an **Execute** method running an **Alter** command, implicitly issues an exclusive lock on the database.

All locks are held in the context of the current transaction. When the current transaction is committed or rolled back, all locks defined within the transaction are automatically released.

---

# NotifyTableChange Element (XMLA)

Article • 12/09/2022

Notifies an instance of Analysis Services that a change has occurred to tables in a specified data source.

## Syntax

XML

```
<Command>
 <NotifyTableChange>
 <Object>...</Object>
 <TableNotifications>...</TableNotifications>
 </NotifyTableChange>
</Command>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">Object</a> , <a href="#">TableNotifications</a>

## Remarks

The **NotifyTableChange** command allows a client application to explicitly notify an Analysis Services instance that one or more tables contained in a data source have been changed. For proactive caching, this notification indicates that relational OLAP (ROLAP) objects based on those tables should be reviewed and updated.

This method of notification is best used for ROLAP objects based on views or named queries defined in a data source view for which changes can be hard to detect and track.

The **Object** element must refer to a data source in the Analysis Services database. If the **Object** element refers to an object other than a data source, an error occurs.

# Restore Element (XMLA)

Article • 12/09/2022

Restores a Analysis Services database from a backup file.

## Syntax

XML

```
<Command>
 <Restore>
 <DatabaseName>...</DatabaseName>
 <DatabaseID>...</DatabaseID>
 <File>...</File>
 <Security>...</Security>
 <AllowOverwrite>...</AllowOverwrite>
 <Password>...</Password>
 <Locations>...</Locations>
 <DbStorageLocation>...</DbStorageLocation>
 </Restore>
</Command>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	Command

Relationship	Element
Child elements	<a href="#">AllowOverwrite</a> , <a href="#">DatabaseName</a> , <a href="#">DatabaseID</a> , <a href="#">File</a> , <a href="#">Locations</a> , <a href="#">Password</a> , <a href="#">Security</a> , <a href="#">DbStorageLocation</a>

## Remarks

The **Restore** command restores an Analysis Services database specified in the **DatabaseName** element from a backup file and optionally restores remote partitions from remote backup files.

Depending on the storage mode used by objects stored in the backup file, the **Restore** command restores information as listed in the following table.

[\[+\] Expand table](#)

Storage mode	Information
Multidimensional OLAP (MOLAP)	Source data, aggregations, and metadata
Hybrid OLAP (HOLAP)	Aggregations and metadata
Relational OLAP (ROLAP)	Metadata

During a **Restore** command, an exclusive lock is placed on the Analysis Services database specified in the **DatabaseName** element. The lock is released after the **Restore** command has completed.

### Important

For each backup file, the user who runs the restore command must have permission to read from the backup location specified for each file. To restore an Analysis Services database that is not installed on the server, the user must also be a member of the server role for that Analysis Services instance. To overwrite an Analysis Services database, the user must have one of the following roles: a member of the server role for the Analysis Services instance, or a member of a database role with Full Control (Administrator) permissions on the database to be restored.

### Note

After restoring an existing database, the user who restored the database might lose access to the restored database. This loss of access can occur if, at the time that the backup was performed, the user was not a member of the server role or was not a member of the database role with Full Control (Administrator) permissions.

# RollbackTransaction Element (XMLA)

Article • 12/09/2022

Rolls back a transaction on the current session with an instance of Analysis Services.

## Syntax

XML

```
<Command>
 <RollbackTransaction />
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	None

## Remarks

The **RollbackTransaction** command rolls back all active transactions, explicitly defined using the **BeginTransaction** element, on the current session. If an active transaction

does not already exist, an error occurs. If an active transaction already exists, the Analysis Services instance decrements the reference count of transactions for the current session to zero, rolling back all active transactions.

# Subscribe Element (XMLA)

Article • 12/09/2022

Subscribes to a trace and returns a rowset that contains the trace events from a Analysis Services instance.

## Syntax

XML

```
<Command>
 <Subscribe>
 <Object>...</Object>
 </Subscribe>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">Object</a>

## Remarks

The **Subscribe** command subscribes to and streams back a rowset from a specified trace on an Analysis Services instance. If an object other than a trace is specified in the **Object** element, an error occurs.

If the **Object** element is not specified, a session trace is defined and subscribed to on the Analysis Services instance. The session trace returns a fixed set of trace events from the current session.

The rowset stream returned by this command is terminated if the client application closes the connection to the Analysis Services instance, or if the session on which the **Subscribe** command is executed is terminated.

# Synchronize Element (XMLA)

Article • 12/09/2022

Synchronizes a Analysis Services database with another existing database.

## Syntax

XML

```
<Command>
 <Synchronize>
 <Source>...</Source>
 <SynchronizeSecurity>...</SynchronizeSecurity>
 <ApplyCompression>...</ApplyCompression>
 <Locations>...</Locations>
 </Synchronize>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">ApplyCompression</a> , <a href="#">Locations</a> , <a href="#">Source</a> , <a href="#">SynchronizeSecurity</a>

# Remarks

The **Synchronize** command synchronizes the target database with a source instance and database specified in the **Source** element. Optionally, the **Synchronize** command synchronizes remote partitions defined on the source database.

Depending on the storage mode used by objects stored in the backup file, the **Synchronize** command synchronizes information as listed in the following table.

 Expand table

Storage mode	Information
Multidimensional OLAP (MOLAP)	Source data, aggregations, and metadata
Hybrid OLAP (HOLAP)	Aggregations and metadata
Relational OLAP (ROLAP)	Metadata

During a **Synchronize** command, a read lock is placed on the source database and a write lock is placed on the target database. Both locks are released after the **Synchronize** command has completed.

# UpdateCells Element (XMLA)

Article • 12/09/2022

Updates cells in a write-enabled cube.

## Syntax

XML

```
<Command>
 <UpdateCells>
 <Cell>...</Cell>
 </UpdateCells>
</Command>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Command</a>
Child elements	<a href="#">Cell</a>

## Remarks

The **UpdateCells** command updates cells in a cube that supports cell writeback.

# XML Elements - Headers

Article • 12/09/2022

The XML for Analysis (XMLA) protocol uses XML elements within the SOAP header to manage protocol-level features, such as session support and the negotiation of supported features.

## In this section

The following topics describe the XMLA header elements implemented by Analysis Services.

 Expand table

Method	Description
<a href="#">BeginSession Element (XMLA)</a>	Uses a SOAP header in a SOAP request message to start a new session on an instance.
<a href="#">EndSession Element (XMLA)</a>	Uses the SOAP header in a SOAP request message to end an existing session on an instance.
<a href="#">Session Element (XMLA)</a>	Uses the SOAP header in a SOAP request message to identify an existing, explicit session on an instance.
<a href="#">ProtocolCapabilities Element (XMLA)</a>	Uses the SOAP header in a SOAP request message to identify protocol capabilities between an instance and a client application.

## Feedback

Was this page helpful?

 Yes

 No

# BeginSession Element (XMLA)

Article • 12/09/2022

Uses a SOAP header in a SOAP request message to start a new session on an instance of Analysis Services.

**Namespace** urn:schemas-microsoft-com:xml-analysis

## Syntax

XML

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
 <soap:Header>
 ...
 <BeginSession
 xmlns="urn:schemas-microsoft-com:xml-analysis" />
 ...
 </soap:Header>
 <soap:Body>
 ...
 </soap:Body>
</soap:Envelope>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	None

## Remarks

The **BeginSession** header element is part of a SOAP request sent to a server instance, and explicitly starts a new session on the instance. The SOAP header returned by the SOAP response contains a **Session** element that identifies the new session. This new session identifier be stored and sent in subsequent SOAP requests using the **Session** header element.

If the **BeginSession** header element is not sent, a session is not explicitly started. If a session is not explicitly started, transactions on that session cannot be managed. In other words, you cannot use the following XML for Analysis (XMLA) commands: **BeginTransaction**, **CommitTransaction**, and **RollbackTransaction**. All XMLA methods and commands executed on an implicitly started session are considered to be atomic transactions.

## Feedback

Was this page helpful?

 Yes

 No

# EndSession Element (XMLA)

Article • 12/09/2022

Uses the SOAP header in a SOAP request message to end an existing session on an instance of Analysis Services.

**Namespace** urn:schemas-microsoft-com:xml-analysis

## Syntax

XML

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
 <soap:Header>
 ...
 <EndSession
 xmlns="urn:schemas-microsoft-com:xml-analysis"
 SessionId="string" />
 ...
 </soap:Header>
 <soap:Body>
 ...
 </soap:Body>
</soap:Envelope>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	None

## Attributes

[Expand table](#)

Attribute	Description
SessionId	Required <b>String</b> attribute that identifies the session to be ended. The server uses a globally unique identifier (GUID) to identify a session.

## Remarks

The **EndSession** header element is part of the SOAP request sent to an existing, explicitly started session on an Analysis Services instance. If the **EndSession** header element is sent, but contains a session identifier that is no longer valid, a SOAP fault is returned that indicates that the session cannot be found.

## Feedback

Was this page helpful?

 Yes

 No

# ProtocolCapabilities Element (XMLA)

Article • 12/09/2022

Uses the SOAP header in a SOAP request message to identify protocol capabilities between an instance of Analysis Services and a client application.

**Namespace** `http://schemas.microsoft.com/analysisservices/2003/engine`

## Syntax

```
XML

<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
 <soap:Header>
 ...
 <ProtocolCapabilities
 xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
 <Capability>...</Capability>
 </ProtocolCapabilities>
 ...
 </soap:Header>
 <soap:Body>
 ...
 </soap:Body>
</soap:Envelope>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Capability</a>

## Remarks

The **ProtocolCapabilities** element enables client applications to negotiate protocol capabilities, such as binary XML or compression support, with a server instance at any time. Protocol negotiation involves the following steps:

1. The client application identifies its protocol capability by sending a SOAP request that includes the **ProtocolCapabilities** element as part of the SOAP header.
2. The instance receives and processes the SOAP request.
3. If the instance has the same protocol capability as that requested, the instance sends a SOAP response that includes the same **ProtocolCapabilities** element sent in the SOAP request, and the protocol has been successfully negotiated. Otherwise, the protocol capabilities are not successfully negotiated, and the instance returns a SOAP fault.

After successfully negotiating protocol capabilities, how long the client application and the instance use a particular protocol depends upon whether the session is explicit or implicit:

- An explicit session is one that is created using the [BeginSession](#) header element. For an explicit session, the negotiated protocol is used until either the client application sends a new **ProtocolCapabilities** element or the session ends.
- An implicit session is one that is created by an instance and not explicitly specified by the client application when submitting a SOAP request. For an implicit session, the negotiated protocol is used only until the SOAP request is completed.

Protocol capabilities do not have to be explicitly negotiated. That is, a client application does not have to include a **ProtocolCapabilities** element as part of the SOAP request. If a SOAP request does not include a **ProtocolCapabilities** element, the instance responds using the same format as the SOAP request.

# Session Element (XMLA)

Article • 12/09/2022

Uses the SOAP header in a SOAP request message to identify an existing, explicit session on an instance of Analysis Services.

**Namespace** urn:schemas-microsoft-com:xml-analysis

## Syntax

XML

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
 <soap:Header>
 ...
 <Session
 xmlns="urn:schemas-microsoft-com:xml-analysis"
 SessionId="string" />
 ...
 </soap:Header>
 <soap:Body>
 ...
 </soap:Body>
</soap:Envelope>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	None

## Attributes

[+] [Expand table](#)

Attribute	Description
SessionId	Required <b>String</b> attribute that identifies the session to be used. The server instance uses a globally unique identifier (GUID) to identify a session.

## Remarks

The **Session** header element identifies an existing, explicitly started session on the instance. The **Session** element is part of the SOAP header in the following types of messages:

- A SOAP response that contains a [BeginSession](#) SOAP header element.
- A SOAP request to identify the session on which to run the [Discover](#) or [Execute](#) method.

A session identifier does not guarantee that a session remains valid. The session specified in the **Session** element can expire. For example, a session can expire if the session times out or the connection associated with the session is disconnected. If the session expires and is no longer valid, the server ends the session and rolls back any transaction currently in process. Any SOAP message sent with a session identifier that is no longer valid fails with a SOAP fault indicating that the specified session cannot be found.

If a **Session** element is not sent as part of a SOAP request, the instance implicitly begins a session for the duration of the [Discover](#) or [Execute](#) method call, and then ends that session once the method call has completed.

# AllowOverwrite Element (XMLEA)

Article • 12/09/2022

Determines whether the parent [Backup](#) or [Restore](#) command attempts to overwrite the target file or database.

## Syntax

XML

```
<Backup> <!-- or Restore -->
...
<AllowOverwrite>...</AllowOverwrite>
...
</Backup>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Backup</a> , <a href="#">Restore</a>
Child elements	None

## Remarks

For **Backup** commands, the **AllowOverwrite** element determines whether the command can overwrite the backup file specified in the **File** element.

For **Restore** elements, the **AllowOverwrite** element determines whether the command can overwrite the Analysis Services database specified in the **DatabaseName** element.

---

 No

# Attribute Element (XMLA)

Article • 12/09/2022

Defines or filters a member in an attribute on which a parent [Insert](#), [Update](#), or [Drop](#) command performs.

## Syntax

XML

```
<Attributes>
 ...
 <Attribute>
 <AttributeName>...</AttributeName>
 <Keys>...</Keys>
 <!-- The following elements are included only for attributes contained
 in the Attributes element of a parent Insert or Update command -->
 <Name>...</Name>
 <Translations>...</Translations>
 <CustomRollup>...</CustomRollup>
 <CustomRollupProperties>...</CustomRollupProperties>
 <UnaryOperator>...</UnaryOperator>
 <SkippedLevels>...</SkippedLevels>
 </Attribute>
 ...
</Attributes>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attributes</a>
Child elements	See the table below.

[ ] [Expand table](#)

Ancestor or Parent	Child Element
Drop, Where	<a href="#">AttributeName</a> , <a href="#">Keys</a>
Insert, Update	<a href="#">AttributeName</a> , <a href="#">CustomRollup</a> , <a href="#">CustomRollupProperties</a> , <a href="#">Keys</a> , <a href="#">Name</a> , <a href="#">SkippedLevels</a> , <a href="#">Translations</a> , <a href="#">UnaryOperator</a>

## Remarks

The **Attribute** element defines the attribute member that is inserted, updated, or deleted, respectively, by the **Insert**, **Update**, or **Drop** command. As these commands can operate only on one attribute member at a time, the [Attributes](#) collection of the **Insert**, **Update**, and **Drop** commands can contain only one **Attribute** element. However, the [Attributes](#) collection of the **Where** element for the **Drop** and **Update** commands can contain more than one **Attribute** element, so that you can filter the attributes to be dropped or updated in a write-enabled dimension.

# Axes Element (XMLA)

Article • 12/09/2022

Contains a collection of [Axis](#) elements representing axis data contained by a [root](#) element that uses the [MDDataSet](#) data type.

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:mddataset">
 ...
 <Axes>
 <Axis>...</Axis>
 </Axes>
 ...
</root>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	Any
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">root</a>
Child elements	<a href="#">Axis</a>

# Remarks

Under the **Axes** element, the **Axis** elements are listed in the order that they occur in the dataset, starting at zero. The **AxisFormat** XMLA property setting determines how **Axis** elements are formatted. For more information about the **AxisFormat** property, see [Supported XMLA Properties \(XMLA\)](#).

An axis represents a set of tuples, in which all tuples in the set have the same dimensionality. A set can be represented in different ways with different advantages. For example, the following set of four tuples can be represented as a collection of two-dimensional tuples or a Cartesian product of two one-dimensional sets.

[] [Expand table](#)

1999	1999	2000	2000
Actual	Budget	Actual	Budget

This set of tuples can be represented either as a collection of two-dimensional tuples:

XML
{ ( 1999, Actual ), ( 1999, Budget ), ( 2000, Actual ), ( 2000, Budget ) }

This set can also be represented as a Cartesian product of two one-dimensional sets:

XML
{ 1999, 2000 } x { Actual, Budget }

The first representation, two-dimensional tuples, is simpler for client tools to use. The second representation, a Cartesian product of one-dimensional sets, uses less space and preserves the multidimensional nature of the set.

The following table lists operations that can be used to define and characterize the structure and members of an axis.

[] [Expand table](#)

Operation	Description
Member	The smallest unit of an axis representing the member of a dimension hierarchy.
Members	A collection of <b>Member</b> objects from the same dimension hierarchy.

Operation	Description
Tuple	A collection of members from different dimension hierarchies.
Tuples	A collection of <b>Tuple</b> objects with the same dimensionality.
Union	A union of sets.
CrossJoin	A Cartesian product of sets.

These operations translate the two-dimensional tuples and the Cartesian product of one-dimensional sets as follows.

## Two-dimensional tuples

XML

```
Tuples (
 Tuple(Member(1999), Member(Actual)),
 Tuple(Member(1999), Member(Budget)),
 Tuple(Member(2000), Member(Actual)),
 Tuple(Member(2000), Member(Budget))
```

## Cartesian product of one-dimensional sets

XML

```
CrossProduct (
 Members(Member(1999), Member(2000)),
 Members(Member(Actual), Member(Budget))
```

A client can use the **AxisFormat** property to request a specific representation.

# Axis Element (XMLA)

Article • 12/09/2022

Contains a set of tuples used to represent a single axis in a multidimensional dataset contained by an [Axes](#) element that uses the [MDDataSet](#) data type, returned by the [Execute](#) method.

## Syntax

XML

```
<Axes>
 ...
 <Axis> <!-- when AxisFormat XMLA property is set to ClusterFormat -->
 <CrossProduct>...</CrossProduct>
 </Axis>
 <Axis> <!-- when AxisFormat XMLA property is set to TupleFormat or
CustomFormat -->
 <Tuples>...</Tuples>
 </Axis>
 ...
</Axes>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Axes</a>
Child elements	<a href="#">CrossProduct</a> or <a href="#">Tuples</a>

## Remarks

The content of the **Axis** element varies depending on the value of the **AxisFormat** XMLA property used by the **Execute** method.

## TupleFormat

When a client application sets the **AxisFormat** property to *TupleFormat*, an axis is represented as a set of tuples. Each **Axis** element contains a **Tuples** element that represents the set of tuples on that axis. Each tuple is represented by using a **Tuple** element that contains **Member** elements from every hierarchy on the axis.

## ClusterFormat

When a client application sets the **AxisFormat** property to *ClusterFormat*, the members on each axis are divided into clusters in which each cluster represents a cross-product between ordered sets of members from each hierarchy. Each **Axis** element consists of one or more **CrossProduct** elements. Every **CrossProduct** element contains a **Members** element for each hierarchy on the axis.

## CustomFormat

When a client application sets the **AxisFormat** property to *CustomFormat*, the value is treated the same as the *TupleFormat* value by an Analysis Services instance.

## Examples

### Description

The following example illustrates the structure of the **Axis** elements when a client specifies *TupleFormat* or *CustomFormat* for the **AxisFormat** XMLA property, given the following members for the axis:

Time hierarchy

Category hierarchy

1999

Actual

1999

Budget

2000

Budget

## Code

XML

```
<Axes>
 <Axis name="Axis0">
 <Tuples>
 <Tuple>
 <Member Hierarchy="Time">
 <UName>[Time].[1999]</UName>
 ...
 </Member>
 <Member Hierarchy="Category">
 <UName>[Scenario].[Actual]</UName>
 ...
 </Member>
 </Tuple>
 <Tuple>
 <Member Hierarchy="Time">
 <UName>[Time].[1999]</UName>
 ...
 </Member>
 <Member Hierarchy="Category">
 <UName>[Scenario].[Budget]</UName>
 ...
 </Member>
 </Tuple>
 <Tuple>
 <Member Hierarchy="Time">
 <UName>[Time].[2000]</UName>
 ...
 </Member>
 <Member Hierarchy="Category">
 <UName>[Scenario].[Budget]</UName>
 ...
 </Member>
 </Tuple>
 </Tuples>
 </Axis>
</Axes>
```

```
 </Member>
 </Tuple>
</Tuples>
</Axis>
...
</Axes>
```

## Description

The following example illustrates the structure of the **Axis** elements when a client specifies *ClusterFormat* for the **AxisFormat** XMLA property, given the following members for the axis:

Time hierarchy

Category hierarchy

Clusters

1999

Actual

Clusters 1

1999

Budget

Clusters 1

2000

Budget

Clusters 1

2001

Budget

Clusters 2

## Code

# AxisInfo Element (XMLA)

Article • 12/09/2022

Represents the metadata of a single axis contained by the parent [AxesInfo](#) element.

## Syntax

XML

```
<AxesInfo>
 ...
 <AxisInfo name="string">
 <HierarchyInfo>...</HierarchyInfo>
 </AxisInfo>
 ...
</AxesInfo>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-n: Required element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">AxesInfo</a>
Child elements	<a href="#">HierarchyInfo</a>

## Attributes

Attribute	Description
Name	Required <b>String</b> attribute. The name of the axis.

## Remarks

In a **root** element that uses the **MDDDataSet** object, an **AxisInfo** element contains a collection of **HierarchyInfo** elements that, combined with the value of the **name** attribute, represents the definition of a single axis returned in the multidimensional dataset.

# BackupRemotePartitions Element (XMLA)

Article • 12/09/2022

Determines whether the parent [Backup](#) command backs up remote partitions associated with the object.

## Syntax

XML

```
<Backup>
 ...
 <BackupRemotePartitions>...</BackupRemotePartitions>
 ...
</Backup>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Backup</a>
Child elements	None

## Remarks

If `BackupRemotePartitions` is set to `True`, a `Locations` element that contains one or more `Location` elements must be included in the `Backup` command, or an error occurs.

# Binding Element (XMLA)

Article • 12/09/2022

Defines an out-of-line binding for an Analysis Services object, such as an attribute in a dimension, for the [Bindings](#) collection of a [Batch](#) or [Process](#) command.

## Syntax

XML

```
<Bindings>
 <Binding xsi:type="DimensionAttributeBinding">...</Binding>
 <!-- or -->
 <Binding xsi:type="MeasureGroupAttributeBinding">...</Binding>
 <!-- or -->
 <Binding xsi:type="PartitionBinding">...</Binding>
</Bindings>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	<a href="#">DimensionAttributeBinding</a> , <a href="#">MeasureGroupAttributeBinding</a> , <a href="#">PartitionBinding</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Bindings</a>
Child elements	None

## Remarks

Binding elements define out-of-line bindings, other than data sources and data source views, for Analysis Services objects to be processed by a **Batch** or **Process** command.

---

# CancelAssociated Element (XMLA)

Article • 12/09/2022

Indicates whether the parent [Cancel](#) element should cancel all associated commands.

## Syntax

XML

```
<Cancel>
 ...
 <ConnectionID>...</ConnectionID>
 ...
</Cancel>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Cancel</a>
Child elements	None

## Remarks

If this element is specified and set to **True**, every corresponding connection, session, and command identified in the parent **Cancel** command is canceled.

---

## Feedback

 Yes

 No

# Capability Element (XMLA)

Article • 12/09/2022

Indicates support for a protocol capability in the parent [ProtocolCapabilities](#) header element.

## Syntax

XML

```
<ProtocolCapabilities>
 ...
 <Capability>...</Capability>
 ...
</ProtocolCapabilities>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">ProtocolCapabilities</a>
Child elements	None

## Remarks

The **Capability** element indicates that a particular capability, such as binary or compression, is supported by either the application that included the **ProtocolCapabilities** header element in the SOAP header of the SOAP request, or by the instance of Analysis Services that included the **ProtocolCapabilities** header element in the SOAP header of the SOAP response. The value of the **Capability** element is the name of the capability to be supported.

Analysis Services supports the capabilities listed in the following table.

  Expand table

Capability name	Description
sx	Binary XML support
xpress	Compression support

# Caption Element (XMLA)

Article • 12/09/2022

Contains information about the caption of the parent [HierarchyInfo](#) or [Member](#) element.

## Syntax

XML

```
<HierarchyInfo> <!-- or Member -->
 ...
 <Caption>...</Caption>
 ...
</HierarchyInfo>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">HierarchyInfo</a> , <a href="#">Member</a>
Child elements	None

## Remarks

For **HierarchyInfo** elements, the **Caption** element contains the name of the property that provides the member captions of the hierarchy. The value is equivalent to the MEMBER\_CAPTION property defined for axis rowsets in the OLE DB for OLAP specification.

For **Member** elements, the **Caption** element contains the caption of the parent **Member** element in the language specified for the XML for Analysis (XMLA) session. If no caption is available, this element contains the unique name of the member.

---

 No

# Cell Element (MDDataSet) (XMLA)

Article • 12/09/2022

Contains information about a single cell contained by a parent [CellData](#) element.

## Syntax

XML

```
<CellData>
 <Cell CellOrdinal="unsignedInt">
 <!-- Zero or more cell property values -->
 <!-- or -->
 <Error>...</Error>
 </Cell>
</CellData>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CellData</a>
Child elements	Zero or more cell property values or <a href="#">Error</a>

## Attributes

Attribute	Description
CellOrdinal	Required <b>unsignedInt</b> attribute. The ordinal position of the cell within the multidimensional dataset.

## Remarks

In the parent **root** element, the **Axes** element is followed by the **CellData** element, a collection of **Cell** elements that contain the property values for each cell returned in the multidimensional dataset. The **Cell** element contains the **CellOrdinal** attribute, which indicates the zero-based ordinal position of the cell within the multidimensional dataset, and one element for each cell property value associated with the cell. Each cell property value in the **Cell** element is defined by a separate XML element. The value of the cell property is the data contained by the XML element, and the name of the cell property, as defined in the **CellInfo** element of the parent root element, corresponds to the name of the XML element.

The following syntax describes a cell property value:

XML

```
<CellProperty xsi:type="string">value</CellProperty>
```

The data type of a cell property value is specified only for the VALUE cell property. The data types of other cell properties are determined by the cell property definition included in the **CellInfo** element. A cell property value element can be excluded if a default value has been specified (by including a **Default** element for a cell property definition contained in the **CellInfo** element) for a cell property, or if no default value has been specified and the value of the cell property is null.

## Cell Property Errors

If a cell property cannot be returned due to an error that occurs on the instance of Analysis Services, such as a calculation error that prevents the value from being returned for a given cell, an **Error** element replaces the contents of the cell property in question. The following XML example describes a cell property error:

XML

```

<Cell CellOrdinal="0">
 <Value xsi:type="xsd:double">
 <Error>
 <ErrorCode>2148497527</ErrorCode>
 <Description>Unknown error</Description>
 </Error>
 </Value>
</Cell>

```

## Calculating Cell Ordinal Values

The axis reference for a cell can be calculated based on a **CellOrdinal** attribute value. Conceptually, cells are numbered in a dataset as if the dataset were a  $p$ -dimensional array, where  $p$  is the number of axes. Cells are addressed in row-major order.

Suppose that a query requests four measures on columns and a crossjoin of two states with four quarters on rows. In following the dataset result, the **CellOrdinal** property for the part of the dataset result shown in bold text is the set {9, 10, 11, 13, 14, 15, 17, 18, 19}. This is the set because the cells are numbered in row-major order, starting with a **CellOrdinal** of 0 for the upper left cell.

[\[+\] Expand table](#)

State	Quarter	Unit sales	Store cost	Store sales	Sales count
California	Q1	16890	14431.09	36175.2	5498
	Q2	18052	15332.02	38396.75	5915
	Q3	18370	15672.83	39394.05	6014
	Q4	21436	18094.5	45201.84	7015
Oregon	Q1	19287	16081.07	40170.29	6184
	Q2	15079	12678.96	31772.88	4799
	Q3	16940	14273.78	35880.46	5432
	Q4	16353	13738.68	34453.44	5196
Washington	Q1	30114	25240.08	63282.86	9906
	Q2	29479	24953.25	62496.64	9654
	Q3	30538	25958.26	64997.38	10007

State	Quarter	Unit sales	Store cost	Store sales	Sales count
	Q4	34235	29172.72	73016.34	11217

Applying the formula shown in the figure, axis k = 0 has  $U_k = 4$  members, and axis k = 1 has  $U_k = 8$  tuples. P = 2 is the total number of axes in the query. Taking the cell that is {California, Q3, Store Cost} as S0, the initial summation is i = 0 to 1. For i = 0, the tuple ordinal on axis 0 of {Store Cost} is 1. For i = 1, the tuple ordinal of {CA, Q3} is 2.

For i = 0,  $E_i = 1$ , so for i = 0 the sum is  $1 * 1 = 1$  and for i = 1, the sum is 2 (tuple ordinal) times 4 (the value of  $E_i$  computed as  $1 * 4$ ), or 8. The sum of 1 + 8 is then 9, the cell ordinal for that cell.

## Example

The following example demonstrates the structure of the **Cell** element, including the **VALUE**, **FORMATTED\_VALUE**, and **FORMAT\_STRING** cell property values for each cell.

```
XML

<CellData>
 <Cell CellOrdinal="0">
 <Value xsi:type="xsd:double">16890</Value>
 <FmtValue>16,890.00</FmtValue>
 <FormatString>Standard</FormatString>
 </Cell>
 <Cell CellOrdinal="1">
 <Value xsi:type="xsd:int">50</Value>
 <FmtValue>50</FmtValue>
 <FormatString>Standard</FormatString>
 </Cell>
 <Cell CellOrdinal="2">
 <Value xsi:type="xsd:double">36175.2</Value>
 <FmtValue>$36,175.20</FmtValue>
 <FormatString>Currency</FormatString>
 </Cell>
</CellData>
```

# CellInfo Element (XMLA)

Article • 12/09/2022

Represents the cell metadata contained by the parent [OlapInfo](#) element.

## Syntax

XML

```
<OlapInfo>
 ...
 <CellInfo>
 <!-- One or more cell property definitions -->
 </CellInfo>
 ...
</OlapInfo>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">OlapInfo</a>
Child elements	One or more cell property definitions

## Remarks

The **CellInfo** element contains a collection of cell properties for the cells included within the multidimensional dataset returned by a **root** element using the **MDDataSet** data type. Each cell property in the **CellInfo** element is defined by a separate XML element, each with a **name** attribute and a **type** attribute. The **name** attribute of the cell property corresponds to the name of the OLE DB for the OLAP cell property represented by the XML element, and the **type** attribute represents the XML data type of the cell property. The name of the XML element is used to identify the value of the cell property for cells contained in the **CellData** element of the **root** element.

The following syntax describes a cell property definition:

XML

```
<CellPropertyDefinition name="string" type="string" />
```

The available properties and their values can be obtained by using the **DISCOVER\_PROPERTIES** request type with the **Discover** method. There is no required order for the properties listed in the **PropertyList** element.

A provider can optionally specify default values for individual member or cell properties in the **AxisInfo** or **CellInfo** section. Default values can provide a smaller result if the property always or almost always has the same value. To indicate a default value for a property, the **Default** element can optionally be specified as a child element of one of the cell property definition elements. Therefore, the absence of a member or cell property in the result indicates that the stated default is the value for the cell property.

## Example

The following example demonstrates how the **VALUE**, **FORMATTED\_VALUE**, and **FORMAT\_STRING** cell properties are represented in the **CellInfo** element.

XML

```
<OlapInfo>
 ...
 <CellInfo>
 <Value name="VALUE"></Value>
 <FmtValue name="FORMATTED_VALUE"></FmtValue>
 <FormatString name="FORMAT_STRING"></FormatString>
 </CellInfo>
</OlapInfo>
```

# CrossProduct Element (XMLA)

Article • 12/09/2022

Contains a cross-product between ordered sets of members from each hierarchy for an [Axis](#) element that uses the [MDDataSet](#) data type, returned by the [Execute](#) method.

## Syntax

XML

```
<Axis>
 ...
 <CrossProduct Size="integer">
 <Members>...</Members>
 </CrossProduct>
 ...
</Axis>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Axis</a>
Child elements	<a href="#">Members</a>

# Attributes

[Expand table](#)

Attribute	Description
Size	Required <b>Integer</b> attribute. Indicates the number of tuples contained in the cross-product represented by the <b>CrossProduct</b> element.

## Remarks

When a client application sets the **AxisFormat** property to *ClusterFormat*, the members on each axis are divided into clusters in which each cluster represents a cross-product between ordered sets of members from each hierarchy. Each cluster is represented by a **CrossProduct** element. Every **CrossProduct** element contains a **Members** element for each hierarchy on the axis. A **CrossProduct** element can contain members from a single hierarchy.

## Example

The following example illustrates the structure of the **CrossProduct** element when a client specifies *ClusterFormat* for the **AxisFormat** XMLA property, given the following members for the axis:

Time hierarchy

Category hierarchy

Clusters

1999

Actual

Clusters 1

1999

Budget

Clusters 1

2000

Budget

Clusters 1

2001

Budget

Clusters 2

XML

```
<Axes>

# Cube Element (OlapInfo) (XMLA)

Article • 12/09/2022

Contains information about a cube for the parent [CubeInfo](#) element.

## Syntax

XML

```
<CubeInfo>
 <Cube>
 <CubeName>...</CubeName>
 <LastDataUpdate>...</LastDataUpdate>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 </Cube>
 ...
</CubeInfo>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CubeInfo</a>
Child elements	<a href="#">CubeName</a> , <a href="#">LastDataUpdate</a> , <a href="#">LastSchemaUpdate</a>

# Cube Element (XMLA)

Article • 12/09/2022

Identifies the cube that contains the dimension represented by the parent [Object](#) element.

## Syntax

XML

```
<Object>
 ...
 <Cube>...</Cube>
 ...
</Object>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Object</a>
Child elements	None

## Remarks

The **Cube** element is an object identifier that contains the name of the cube that contains the dimension represented by the **Object** element.

---

## Feedback

Was this page helpful?

 Yes

 No

# CubeID Element (XMLA)

Article • 12/09/2022

Identifies a cube within a parent element that contains an object reference.

## Syntax

XML

```
<Object> <!-- or one of the elements listed below in the Element
relationships table -->
...
<CubeID>...</CubeID>
...
</Object>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Cardinality
Source	1-1: Required element that occurs once and only once.
Target	1-1: Required element that occurs once and only once.
All others	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Object</a> , <a href="#">ParentObject</a> , <a href="#">Source</a> , <a href="#">Target</a>
Child elements	None

# CubeInfo Element (XMLA)

Article • 12/09/2022

Contains the cube metadata contained by the parent [OlapInfo](#) element.

## Syntax

XML

```
<OlapInfo>
 ...
 <CubeInfo>
 <Cube>...</Cube>
 </CubeInfo>
 ...
</OlapInfo>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">OlapInfo</a>
Child elements	<a href="#">Cube</a>

## Remarks

The **CubeInfo** element contains one **Cube** element for each cube referenced in the multidimensional dataset.

 **Note**

Analysis Services returns only a single **Cube** element in this collection because Analysis Services does not support statements that reference multiple cubes in the FROM clause of the Multidimensional Expressions (MDX) language.

---

 No

# CustomRollup Element (XMLA)

Article • 12/09/2022

Contains the custom rollup formula for an attribute member represented by the parent [Attribute](#) element.

## Syntax

XML

```
<Attribute>
 ...
 <CustomRollup>...</CustomRollup>
 ...
</Attribute>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attribute</a>
Child elements	None

## Remarks

The **CustomRollup** element contains a Multidimensional Expressions (MDX) expression that defines the rollup behavior of the attribute member defined by the parent **Attribute** element.

---

## Feedback

Was this page helpful?

Yes

No

# CustomRollupProperties Element (XMLA)

Article • 12/09/2022

Contains the custom rollup properties for an attribute member represented by the parent [Attribute](#) element.

## Syntax

XML

```
<Attribute>
 ...
 <CustomRollupProperties>...</CustomRollupProperties>
 ...
</Attribute>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attribute</a>
Child elements	None

## Remarks

The **CustomRollupProperties** element contains a Multidimensional Expressions (MDX) expression that defines the custom rollup properties of the attribute member defined by the parent **Attribute** element.

# Database Element (XMLA)

Article • 12/09/2022

Identifies the database that contains the dimension represented by the parent [Object](#) element.

## Syntax

XML

```
<Object>
 ...
 <Database>...</Database>
 ...
</Object>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Object</a>
Child elements	None

## Remarks

The **Database** element is an object identifier that contains the name of the Analysis Services database that contains the dimension represented by the **Object** element.

---

## Feedback

Was this page helpful?

 Yes

 No

# DatabaseID Element (XMLA)

Article • 12/09/2022

Identifies a database within a parent element that contains an object reference.

## Syntax

XML

```
<Object> <!-- or one of the elements listed below in the Element
relationships table -->
...
<DatabaseID>...</DatabaseID>
...
</Object>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Cardinality
Source, Target	1-1: Required element that occurs once and only once.
All others	0-1: Optional element that can occur once and only once.

## Element relationships

## Feedback

Was this page helpful?

 Yes

 No

# DatabaseName Element (XMLA)

Article • 12/09/2022

Identifies the Analysis Services database to be restored by the parent [Restore](#) command.

## Syntax

XML

```
<Restore>
 ...
 <DatabaseName>...</DatabaseName>
 ...
</Restore>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Restore</a>
Child elements	None

## Remarks

The **DatabaseName** element identifies the database into which the **Restore** command restores a backup file. If this element is not specified or contains an empty string, the name of the database contained in the backup file is used.

If the database already exists on the target instance, an error occurs unless the **AllowOverwrite** element for the parent **Restore** command is set to **True**.

 No

# DataSource Element (XMLA)

Article • 12/09/2022

Contains an out-of-line data source binding for the parent [Batch](#) or [Process](#) element.

## Syntax

XML

```
<Batch> <!-- or Process>
...
<DataSource>
 <DatabaseID>...</DatabaseID>
 <DataSourceID>...</DataSourceID>
</DataSource>
...
</Batch>
```

## Element characteristics

  [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

  [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Batch</a> , <a href="#">Process</a>
Child elements	<a href="#">DatabaseID</a> , <a href="#">DataSourceID</a>

## Remarks

The **DataSource** element represents an out-of-line binding to a data source, used by the **Batch** or **Process** command to temporarily override the data source binding for Analysis Services objects processed by the command.

---

# DataSourceID Element (XMLA)

Article • 12/09/2022

Identifies a data source used by a [Location](#) element during a [Backup](#), [Restore](#), or [Synchronize](#) command.

## Syntax

XML

```
<Location>
 ...
 <DataSourceID>...</DataSourceID>
 ...
</Location>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Location</a>
Child elements	None

## Remarks

The **DataSourceID** element contains the name of the data source on the source instance that identifies the remote instance on which remote partition information is to be backed up, restored, or synchronized.

---

## Feedback

Was this page helpful?

Yes

No

# DataSourceType Element (XMLA)

Article • 12/09/2022

Indicates whether a [Location](#) element specified for a [Restore](#) or [Synchronize](#) command is local or remote.

## Syntax

XML

```
<Location>
 ...
 <DataSourceType>...</DataSourceType>
 ...
</Location>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Remote</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Location</a>
Child elements	None

## Remarks

The **DataSourceType** element determines whether the data source defined by the **Location** element contains a local data source or a remote data source.

The value of this element is limited to one of the strings listed in the following table.

 Expand table

Value	Description
<i>Local</i>	<p>The <b>Location</b> element defines a local data source. If this value is used, the <b>Restore</b> and <b>Synchronize</b> commands use the information defined in the <b>Location</b> element to update the data source, retrieved from either the backup file specified in the <b>File</b> element for the <b>Backup</b> command or the database specified in the <b>Source</b> element for the <b>Synchronize</b> command, identified in the <b>DataSourceID</b> element of the <b>Location</b> element.</p>
	<p>This value allows objects that use relational OLAP (ROLAP) storage, after being restored or synchronized, to use a different database for their data and metadata.</p> <p>Note: ROLAP data, such as data in dimension tables or writeback tables, is not restored or synchronized. Only metadata for ROLAP objects is restored or synchronized.</p>
<i>Remote</i>	<p>The <b>Location</b> element defines a remote data source. If this value is used, the <b>Restore</b> and <b>Synchronize</b> commands use the information defined in the <b>Location</b> element to restore or synchronize remote partitions, retrieved from either the backup file specified in the <b>File</b> element of the <b>Backup</b> command or the database specified in the <b>Source</b> element for the <b>Synchronize</b> command, to the remote instance identified in the <b>DataSourceID</b> of the <b>Location</b> element.</p>

# DataSourceView Element (XMLA)

Article • 12/09/2022

Contains an out-of-line data source view binding for the parent [Batch](#) or [Process](#) element.

## Syntax

XML

```
<Batch> <!-- or Process>
...
<DataSourceView>
 <DatabaseID>...</DatabaseID>
 <DataSourceViewID>...</DataSourceViewID>
</DataSourceView>
...
</Batch>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Batch</a> , <a href="#">Process</a>
Child elements	<a href="#">DatabaseID</a> , <a href="#">DataSourceViewID</a>

## Remarks

The **DataSourceView** element represents an out-of-line binding to a data source view, used by the **Batch** or **Process** command to temporarily override the data source view binding for Analysis Services objects processed by the command.

# DbSchemaName Element (XMLA)

Article • 12/09/2022

Contains the name of the schema used by the parent [TableNotification](#) element in the table identified by the [DbTableName](#) element.

## Syntax

XML

```
<TableNotification>
 ...
 <DbSchemaName>...</DbSchemaName>
 ...
</TableNotification>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">TableNotification</a>
Child elements	None

## Remarks

---

# Feedback

Was this page helpful?

 Yes

 No

# DbStorageLocation Element

Article • 12/09/2022

Specifies the folder where Analysis Services creates and manages all the database data and metadata files.

## Syntax

XML

```
<Database>
...
<ddl100_100:DbStorageLocation>...</ddl100_100:DbStorageLocation>
...
</Database>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	""
Cardinality	0-1: Optional element that can occur one time only.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	None

## Remarks

The **DbStorageLocation** database property must be set to an existing UNC folder path or an empty string. An empty string is the default server data folder. If the folder doesn't exist, an error will be raised when executing a **Create**, **Attach**, or **Alter** command.

In addition, the **DbStorageLocation** database property cannot be set to point to the server data folder or any of its subfolders. If the location points to the server data folder or any of its subfolders, an error will be raised when executing a **Create**, **Attach**, or **Alter** command.

 Yes

 No

# DefaultDetailsPosition Element (XML)

Article • 12/09/2022

Contains information about the position of the element in a collection of elements.

## Syntax

XML

```
<RelationshipEndVisualizationProperties>
 ...
 <DefaultDetailsPosition>...</DefaultDetailsPosition>
 ...
</RelationshipEndVisualizationProperties>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	-1
Cardinality	0-1: Optional element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">RelationshipEndVisualizationProperties</a>
Child elements	None

## Remarks

For RelationshipEndVisualizationProperties elements, the DefaultDetailsPosition element contains the position of the default detail element in a collection of details. The default value of **false** indicates there is no default detail to be used.

---

## Feedback

Was this page helpful?

Yes

No

# DeleteWithDescendants Element (XMLA)

Article • 12/09/2022

Indicates whether the descendants of attribute members are also deleted by the parent [Drop](#) command.

## Syntax

XML

```
<Drop>
 ...
 <DeleteWithDescendants>...</DeleteWithDescendants>
 ...
</Drop>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Drop</a>
Child elements	None

## Remarks

The **DeleteWithDescendants** element determines whether the **Drop** command should delete the attribute members identified by the [Where](#) element, but also that the descendants of those attribute members are to be dropped as well.

 **Note**

This element applies only to attribute members in parent-child hierarchies.

# DisplayInfo Element (XMLA)

Article • 12/09/2022

Contains display information for the parent [HierarchyInfo](#) or [Member](#) element.

## Syntax

XML

```
<HierarchyInfo> <!-- or Member -->
...
<DisplayInfo>...</DisplayInfo>
...
</HierarchyInfo>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	unsignedInt
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">HierarchyInfo</a> , <a href="#">Member</a>
Child elements	None

## Remarks

The **DisplayInfo** element contains various items of information that help a client application render the parent **HierarchyInfo** or **Member** element. The value is equivalent to the DISPLAY\_INFO property defined for axis rowsets in the OLE DB for OLAP specification.

# Exception Element (XMLA)

Article • 12/09/2022

Indicates that an exception was returned from a [Discover](#) or [Execute](#) method call.

Namespace `http://schemas.microsoft.com/analysisservices/2003/exception`

## Syntax

XML
<pre>&lt;root&gt;   ...   &lt;Exception /&gt;   ... &lt;/root&gt;</pre>

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<code>root</code>
Child elements	None

## Remarks

If an error occurs during the execution of a **Discover** method call or a single XMLA command in an **Execute** method call that prevents the method or command from completing, the **root** element for that method or command contains an **Exception** element and a **Messages** element. The **Exception** element indicates that an error which prevented the method or command from successfully executing occurred, and the **Messages** element contains the list of error or warning messages related to the error.

# File Element (XMLE)

Article • 12/09/2022

Identifies a file to be used by the parent [Backup](#) or [Restore](#) command, or by the parent [Location](#) element.

## Syntax

XML

```
<Backup> <!-- or one of the elements listed below in the Element
relationships table -->
...
 <File>...</File>
...
</Backup>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Backup</a> , <a href="#">Location</a> , <a href="#">Restore</a>
Child elements	None

## Remarks

The **File** element contains a UNC file name, and the parent element determines the use of the **File** element.

For **Backup** commands, the **File** element determines the name of the backup file created by the **Backup** command. If a path is not specified as part of the file name, the path specified in the **BackupDir** configuration property for the instance of Analysis Services is used. If the specified file already exists, an error occurs unless the **AllowOverwrite** element of the parent **Backup** command is set to **True**.

For **Restore** commands, the **File** element determines the name of the backup file to be restored by the **Restore** command.

For **Location** elements, the **File** element describes a remote backup file for an Analysis Services instance that contains remote partitions.

# Folder Element (XMLA)

Article • 12/09/2022

Contains a file system storage location to be updated for a [Location](#) element during a [Restore](#) or [Synchronize](#) command.

## Syntax

```
XML

<Folders>
 ...
 <Folder>
 <Original>...</Original>
 <New>...</New>
 </Folder>
 ...
</Folders>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Folders</a>
Child elements	<a href="#">New</a> , <a href="#">Original</a>

## Remarks

The **Folder** element, if specified, changes the storage locations of objects contained either by the backup file (for **Restore** commands) or the database on the source instance (for **Synchronize** commands) that match the value of the **Original** element to the value of the **New** element.

# FolderPosition Element (XML)

Article • 12/09/2022

Contains information about the position of the element in a collection of elements.

## Syntax

XML

```
<RelationshipEndVisualizationProperties>
 ...
 <FolderPosition>...</FolderPosition>
 ...
</RelationshipEndVisualizationProperties>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	-1
Cardinality	0-1: Optional element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">RelationshipEndVisualizationProperties</a>
Child elements	None

## Remarks

For **RelationshipEndVisualizationProperties** elements, the **FolderPath** element contains the position of the default folder element in a collection of folders. The default value of **false** indicates there is no default folder to be used.

# IsDefaultImage Element (XML)

Article • 12/09/2022

Indicates that it is possible to obtain the default image for this entity by navigating this relationship to the other table and fetching the member that has the attribute, IsDefaultImage.

## Syntax

XML

```
<RelationshipEndVisualizationProperties>
 ...
 <IsDefaultImage>...</IsDefaultImage>
 ...
</RelationshipEndVisualizationProperties>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	false
Cardinality	0-1: Optional element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">RelationshipEndVisualizationProperties</a>
Child elements	None

## Remarks

For `RelationshipEndVisualizationProperties` elements, the `IsDefaultImage` element indicates that the default image for this entity can be obtained by navigating to the other end of this relationship. The default value of `false` indicates there is no default image to be obtained.

# Key Element (XMLA)

Article • 12/09/2022

Contains a member key value for an attribute member.

## Syntax

XML

```
<Keys>
 ...
 <Key>...</Key>
 ...
</Keys>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Any
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Keys</a>
Child elements	None

## Remarks

The data type used by this element should match the data type of the appropriate key column of the specified attribute. If **Key** elements are not specified for a parent **Attribute** element, the **AttributeName** and **Name** elements specified in the parent **Attribute** element are used to identify the attribute member to be modified.

# LName Element (XMLA)

Article • 12/09/2022

Contains information about unique level names for the parent [HierarchyInfo](#) or [Member](#) element.

## Syntax

XML

```
<HierarchyInfo> <!-- or Member -->
...
<LName>...</LName>
...
</HierarchyInfo>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">HierarchyInfo</a> , <a href="#">Member</a>
Child elements	None

## Remarks

For **HierarchyInfo** elements, this element contains the name of the property that provides the unique level names of the hierarchy. The value is equivalent to the LEVEL\_UNIQUE\_NAME property defined for axis rowsets in the OLE DB for OLAP specification.

For **Member** elements, this element contains the unique name of the level in the hierarchy that contains the member represented by the parent **Member** element.

# LNum Element (XMLA)

Article • 12/09/2022

Contains information about level ordinal positions for the parent [HierarchyInfo](#) or [Member](#) element.

## Syntax

XML

```
<HierarchyInfo> <!-- or Member -->
...
<LNum>...</LNum>
...
</HierarchyInfo>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	int
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">HierarchyInfo</a> , <a href="#">Member</a>
Child elements	None

## Remarks

For **HierarchyInfo** elements, the **LNum** element contains the name of the property that provides the level ordinal positions of the hierarchy. The value is equivalent to the **LEVEL\_NUMBER** property defined for axis rowsets in the OLE DB for OLAP specification.

For **Member** elements, the **LNum** element contains the zero-based ordinal position, from the root level of the hierarchy, of the member represented by the parent **Member** element. A value of zero represents the root level of the hierarchy.

---

 Yes

 No

# Location Element (XMLA)

Article • 12/09/2022

Contains information about a remote server for the parent [Backup](#), [Restore](#), or [Synchronize](#) command.

## Syntax

XML

```
<Backup> <!-- or one of the elements listed below in the Element
relationships table -->
...
<Location>
```

XML

```
<File>...</File> <!-- for Backup and Restore only -->
<DataSourceID>...</DataSourceID>
<DataSourceType>...</DataSourceType> <!-- for Restore and Synchronize only -
-->
<ConnectionString>...</ConnectionString> <!-- for Restore and Synchronize
only -->
<Folders>...</Folders> <!-- for Restore and Synchronize only -->
```

XML

```
</Location>
...
</Backup>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None

Characteristic	Description
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Backup</a> , <a href="#">Restore</a> , <a href="#">Synchronize</a>
Child elements	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Child Element
<a href="#">Backup</a>	<a href="#">DataSourceID</a> , <a href="#">File</a>
<a href="#">Restore</a>	<a href="#">ConnectionString</a> , <a href="#">DataSourceID</a> , <a href="#">DataSourceType</a> , <a href="#">File</a> , <a href="#">Folders</a>
<a href="#">Synchronize</a>	<a href="#">ConnectionString</a> , <a href="#">DataSourceID</a> , <a href="#">DataSourceType</a> , <a href="#">Folders</a>

## Remarks

For **Backup** commands, the **Location** element provides information about creating a remote backup file for a remote instance of Analysis Services.

For **Restore** commands, the **Location** element provides information about identifying and connecting to a remote Analysis Services instance, as well as the remote backup file used to restore remote partitions on that remote instance.

For **Synchronize** commands, the **Location** element describes either a data source to be used by the target instance or a remote instance defined on the source instance that must be synchronized with the target instance, depending on the value of the **DataSourceType** element for the parent **Synchronize** command.

# Member Element (XMLA)

Article • 12/09/2022

Represents a single member in a parent [Members](#) or [Tuple](#) element.

## Syntax

XML

```
<Members>
 ...
 <Member>
 <UName>...</UName>
 <Caption>...</Caption>
 <LName>...</LName>
 <LNum>...</LNum>
 <DisplayInfo>...</DisplayInfo>
 </Member>
 ...
</Members>
<!-- or -->
<Tuple>
 ...
 <Member Hierarchy="string">
 <UName>...</UName>
 <Caption>...</Caption>
 <LName>...</LName>
 <LNum>...</LNum>
 <DisplayInfo>...</DisplayInfo>
 </Member>
 ...
</Tuple>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

# Element relationships

# Members Element (XMLA)

Article • 12/09/2022

Contains a collection of [Member](#) elements contained by the parent [CrossProduct](#) element.

## Syntax

XML

```
<CrossProduct>
 <Members Hierarchy="string">
 <Member>...</Member>
 </Members>
 ...
</CrossProduct>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CrossProduct</a>
Child elements	<a href="#">Member</a>

## Attributes

Attribute	Description
Hierarchy	Required <b>String</b> attribute. The name of the hierarchy to which the members contained by the <b>Members</b> element belong.

## Remarks

When a client application sets the **AxisFormat** property to *ClusterFormat*, the members on each axis are divided into clusters in which each cluster represents a cross-product between ordered sets of members from each hierarchy. Each **Axis** element consists of one or more **CrossProduct** elements. Every **CrossProduct** element contains a **Members** element for each hierarchy on the axis. The **Members** element, in turn, contains one **Member** element for each member of the specified hierarchy included in the cross-product.

## Example

The following example illustrates the structure of the **Members** element when a client specifies *ClusterFormat* for the **AxisFormat** XMLA property, given the following members for the axis:

Time hierarchy

Category hierarchy

Clusters

1999

Actual

Clusters 1

1999

Budget

Clusters 1

2000

Budget

Clusters 1

2001

Budget

Clusters 2

XML

```
<Axes>
 <Axis name="Axis0">
 <CrossProduct Size = "4">
 <Members Hierarchy="Time">
 <Member>
 <UName>[Time].[1999]</UName>
 ...
 </Member>
 <Member>
 <UName>[Time].[2000]</UName>
 ...
 </Member>

# Message Element (XMLA)

Article • 12/09/2022

Contains a message returned from an instance of Analysis Services by a [Discover](#) or [Execute](#) method call.

## Syntax

```
XML

<Messages>
 ...
 <Message>
 <Error>...</Error>
 <!-- or -->
 <Warning>...</Warning>
 </Message>
 ...
</Messages>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Messages</a>
Child elements	<a href="#">Error</a> , <a href="#">Warning</a>

## Remarks

This element is used in cases where a **Discover** method call or a single XMLA command within an **Execute** method call completes successfully, but with errors or warnings. In such cases, a **Messages** element is added to the root element after all other elements, which in turn contains one or more **Message** elements. Each **Message** element represents a single message, either an error or a warning, returned by the Analysis Services instance.

---

# Mode Element (XMLA)

Article • 12/09/2022

Identifies the mode to be used by the parent [Lock](#) element when creating a lock on a specified object.

## Syntax

XML

```
<Lock>
 ...
 <Mode>...</Mode>
 ...
</Lock>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Lock</a> , <a href="#">Unlock</a>
Child elements	None

## Remarks

The parent **Lock** element uses the **Mode** element to determine the type of lock to create on an object. The value of this element is limited to one of the strings listed in the following table.

  Expand table

Value	Description
<i>CommitShared</i>	A shared lock is established on the specified object. Other shared locks can be created for the same object.  A shared lock prevents transactions containing write operations, such as an <a href="#">Execute</a> method call running an <a href="#">Alter</a> command, on a specified object, from committing until the shared lock is removed. A shared lock does not prevent transactions containing read operations, such as a <a href="#">Discover</a> method call or an <a href="#">Execute</a> method call running a <a href="#">Statement</a> command, from committing.
<i>CommitExclusive</i>	An exclusive lock is established on the specified object. Other shared or exclusive locks cannot be created for the same object.  An exclusive lock prevents transactions containing either read or write operations on a specified object from committing until the exclusive lock is removed.

# MoveWithDescendants Element (XMLA)

Article • 12/09/2022

Indicates whether the descendants of attribute members are also updated by the parent [Update](#) command.

## Syntax

XML

```
<Update>
 ...
 <MoveWithDescendants>...</MoveWithDescendants>
 ...
</Update>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Update</a>
Child elements	None

## Remarks

The **MoveWithDescendants** element determines whether the **Update** command should not just update the attribute members identified by the **Attributes** element, but also that the descendants of those attribute members are to be updated as well.

 **Note**

This element applies only to attribute members in parent-child hierarchies.

# Name Element (XMLA)

Article • 12/09/2022

Contains the name of an attribute member for the parent [Attribute](#) or [Translation](#) element.

## Syntax

XML
<pre>&lt;Attribute&gt; &lt;!-- or Translation --&gt; ... &lt;Name&gt;...&lt;/Name&gt; ... &lt;/Attribute&gt;</pre>

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	See the table below.

[+] Expand table

Ancestor or Parent	Cardinality
Attribute	1-1: Required element that occurs once and only once.
Translation	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attribute</a> , <a href="#">Translation</a>
Child elements	None

## Remarks

For **Attribute** elements, the **Name** element contains the name of the attribute member to be inserted or updated during, respectively, the **Insert** or **Update** command.

For **Translation** elements, the **Name** element contains the caption of the attribute member, in the language specified by the **Language** element of the parent **Translation** object. If the **Name** element is not specified or contains an empty string, the value of the **Name** element for the **Attribute** element that contains the **Translation** element is used.

# New Element (XMLA)

Article • 12/09/2022

Contains the new file system storage location used by a [Folder](#) element.

## Syntax

XML

```
<Folder>
 ...
 <New> ... </New>
 ...
</Folder>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Folder</a>
Child elements	None

## Remarks

The **New** element contains a UNC path that replaces the value of the **Original** element contained by the parent **Folder** element for all objects restored or synchronized, respectively, during a **Restore** or **Synchronize** command. The value of the **Original** element is compared to the value of the **StorageLocation** element for each cube, measure group, or partition and, if a match is found, the value of this element is used to update the **StorageLocation** of the object during restoration or synchronization.

# Object Element (Dimension) (XMLA)

Article • 12/09/2022

Contains an object reference for the dimension on which the parent [Insert](#), [Update](#), or [Drop](#) command is executed.

## Syntax

```
XML

<Insert> <!-- or any of the parent elements in the Element relationships
table -->
...
<Object>
 <Database>...</Database>
 <Cube>...</Cube>
 <Dimension>...</Dimension>
</Object>
...
</Insert>
```

## Element characteristics

# Object Element (XMLE)

Article • 12/09/2022

Contains an object reference used by the parent element.

## Syntax

XML

```
<Alter> <!-- or any of the parent elements in the Element relationships
table -->
...
<Object>
 <!-- One or more object identifiers, depending on the parent element -
->
 </Object>
...
</Alter>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	See the table below.

[+] Expand table

Ancestor or Parent	Cardinality
Alter	0-1: Optional element that can occur once and only once.
All others	1-1: Required element that occurs once and only once.

## Element relationships

Relationship	Element
Parent elements	<a href="#">Alter</a> , <a href="#">Backup</a> , <a href="#">ClearCache</a> , <a href="#">Delete</a> , <a href="#">DesignAggregations</a> , <a href="#">Lock</a> , <a href="#">NotifyTableChange</a> , <a href="#">Process</a> , <a href="#">Subscribe</a> , <a href="#">Synchronize</a>
Child elements	Required Analysis Services Scripting Language (ASSL) elements. Specified by listing the ID elements of the object and its ancestors (excluding the <b>Server</b> object.) For example, the following <b>Object</b> element identifies a partition:

```

<Object>

<DatabaseID> Adventure Works DW Multidimensional 2012 </DatabaseID>

<CubeID> Adventure Works </CubeID>

<MeasureGroupID> Internet Sales </MeasureGroupID>

<PartitionID> Internet_Sales_2001 </PartitionID>

</Object>

```

## Remarks

The order in which identifiers appear is not important.

For **Alter** elements, the instance of Analysis Services is used as the default object if the **Object** element is not specified.

# ObjectDefinition Element (XMLA)

Article • 12/09/2022

Contains one or more Analysis Services Scripting Language (ASSL) elements, used to create or alter objects on an instance of Analysis Services.

## Syntax

```
XML

<Create> <!-- or Alter -->
...
<ObjectDefinition>
 <!-- One or more ASSL elements -->
</ObjectDefinition>
...
</Create>
```

## Element characteristics

[] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[] Expand table

Relationship	Element
Parent elements	<a href="#">Alter</a> , <a href="#">Create</a>
Child elements	Required ASSL elements. One or more ASSL elements, used to define Analysis Services objects. For more information about ASSL, see <a href="#">Properties (XMLA)</a> .

# Remarks

## Example

The following example creates an empty database named **Test Database** on an Analysis Services instance.

```
XML

<Create
 xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
 <ObjectDefinition>
 <Database xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <Name>Test Database</Name>
 <Description>A test database.</Description>
 </Database>
 </ObjectDefinition>
</Create>
```

# OlapInfo Element (XMLA)

Article • 12/09/2022

Contains the axis and cell metadata contained by a [root](#) element that uses the [MDDataSet](#) data type.

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:mddataset">
 ...
 <OlapInfo>
 <CubeInfo>...</CubeInfo>
 <AxesInfo>...</AxesInfo>
 <CellInfo>...</CellInfo>
 </OlapInfo>
 ...
</root>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">root</a>
Child elements	<a href="#">AxesInfo</a> , <a href="#">CellInfo</a> , <a href="#">CubeInfo</a>

## Remarks

The **OLAPInfo** section of a **root** element using the **MDDDataSet** data type provides metadata about the cube, the axes of the multidimensional result, and the properties of the cells included the result.

# Original Element (XMLA)

Article • 12/09/2022

Contains the original file system storage location used by a [Folder](#) element.

## Syntax

XML

```
<Folder>
 ...
 <Original>...</Original>
 ...
</Folder>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Folder</a>
Child elements	None

## Remarks

The **Original** element contains a UNC path to be replaced with the value of the [New](#) element contained by the parent **Folder** element for all objects restored or synchronized, respectively, during a [Restore](#) or [Synchronize](#) command. The value of this element is compared to the value of the [StorageLocation](#) element for each cube, measure group, or partition and, if a match is found, the value of the **New** element is used to update the [StorageLocation](#) of the object during restoration or synchronization.

# Parallel Element (XMLA)

Article • 12/09/2022

Specifies how many processing jobs can run in parallel using the parent [Batch](#) command.

## Syntax

XML

```
<Batch>
 ...
 <Parallel maxParallel="Integer">
 <!-- An XMLA process command -->
 </Parallel>
 ...
</Batch></pre>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Batch</a>
Child elements	<a href="#">Process Element</a>

# Attributes

 Expand table

Attribute	Description
maxParallel	Optional <b>Integer</b> attribute. Indicates the maximum number of threads on which to run commands in parallel. If not specified or set to 0, the instance of Analysis Services determines an optimal number of threads based on the number of processors available on the computer.

## Remarks

---

## Feedback

 Yes

 No

# Parameter Element (XMLA)

Article • 12/09/2022

Contains the name and value of a parameter used by the [Execute](#) method.

## Syntax

XML

```
<Parameters>
...
<Parameter>
 <Name>...</Name>
 <Value>...</Value>
</Parameter>
...
</Parameters>
```

## Element characteristics

  [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

  [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Parameters</a>
Child elements	<a href="#">Name</a> , <a href="#">Value</a>

## Remarks

Some XML for Analysis (XMLA) commands, such as the [Process](#) command, can require additional information. The **Parameter** element provides a mechanism for providing additional information, including chunked information, for an XMLA command.

# Parameters Element (XMLA)

Article • 12/09/2022

Contains a collection of [Parameter](#) elements used by the [Execute](#) method.

Namespace: `urn:schemas-microsoft-com:xml-analysis`

## Syntax

XML
<pre>&lt;Execute&gt; ... &lt;Parameters&gt;     &lt;Parameter&gt;...&lt;/Parameter&gt; &lt;/Parameters&gt; ... &lt;/Execute&gt;</pre>

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Execute</a>
Child elements	<a href="#">Parameter</a>

## Remarks

Some XML for Analysis (XMLA) commands, such as the [Process](#) command, can require additional information. The **Parameters** element provides a mechanism for providing additional information, including chunked information, for an XMLA command.

If the XMLA command does not use the **Parameters** element, the element can be omitted when calling the [Execute](#) method.

# ParentObject Element (XMLA)

Article • 12/09/2022

Contains the identifier of the parent object under which to create the objects defined by the parent [Create](#) element.

## Syntax

```
XML

<Create>
 ...
 <ParentObject>
 <!-- Object reference -->
 </ParentObject>
 ...
</Create>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Create</a>
Child elements	Required Analysis Services Scripting Language (ASSL) elements. Specified by listing the ID elements of the object and its ancestors (excluding the <a href="#">Server</a> object.) For example, the following <a href="#">ParentObject</a> element identifies a partition:

Relationship	Element
	<pre>&lt;ParentObject&gt;  &lt;DatabaseID&gt;Adventure Works DW Multidimensional 2012 &lt;/DatabaseID&gt;  &lt;CubeID&gt;Adventure Works &lt;/CubeID&gt;  &lt;MeasureGroupID&gt;Internet Sales &lt;/MeasureGroupID&gt;  &lt;PartitionID&gt;Internet_Sales_2001 &lt;/PartitionID&gt;  &lt;/ParentObject&gt;</pre>

## Remarks

The order in which identifiers appear is not important.

## Example

The following example creates the **Market Basket** mining structure, included in the sample Analysis Services database.

XML
<pre>&lt;Create xmlns="http://schemas.microsoft.com/analysisservices/2003/engine"&gt;   &lt;ParentObject&gt;     &lt;DatabaseID&gt;database&lt;/DatabaseID&gt;   &lt;/ParentObject&gt;   &lt;ObjectDefinition&gt;     &lt;MiningStructure xmlns:xsd="http://www.w3.org/2001/XMLSchema"       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"&gt;       &lt;ID&gt;Market Basket&lt;/ID&gt;       &lt;Name&gt;Market Basket&lt;/Name&gt;       &lt;Source xsi:type="DataSourceViewBinding"&gt;         &lt;DataSourceViewID&gt;Adventure Works DW&lt;/DataSourceViewID&gt;       &lt;/Source&gt;       &lt;Language&gt;1033&lt;/Language&gt;       &lt;Collation&gt;Latin1_General_CI_AS&lt;/Collation&gt;       &lt;Columns&gt;         &lt;Column xsi:type="ScalarMiningStructureColumn"&gt;           &lt;ID&gt;Order Number&lt;/ID&gt;           &lt;Name&gt;Order Number&lt;/Name&gt;           &lt;IsKey&gt;true&lt;/IsKey&gt;           &lt;Type&gt;Text&lt;/Type&gt;           &lt;Content&gt;Key&lt;/Content&gt;           &lt;KeyColumns&gt;</pre>

# Password Element (XMLA)

Article • 12/09/2022

Determines the password to be used by the parent [Backup](#) or [Restore](#) command for encrypting or decrypting a backup file.

## Syntax

### XML

```
<Backup> <!-- or Restore -->
...
<Password>...</Password>
...
</Backup>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Backup</a> , <a href="#">Restore</a>
Child elements	None

## Remarks

For **Backup** commands, if the **Password** element is not included or contains an empty string, the backup file is not encrypted.

For **Restore** commands, if the **Password** element is not included or contains an empty string while attempting to restore an encrypted backup file, an error occurs.

If **Location** elements are included in either a **Backup** or a **Restore** command, the same **Password** element is used for both backup and remote backup files.

# Properties Element (XMLA)

Article • 12/09/2022

Contains XML for Analysis (XMAL) properties used by the [Discover](#) and [Execute](#) methods.

## Syntax

```
XML

<Discover> <!-- or Execute -->
...
<Properties>
 <PropertyList>...</PropertyList>
</Properties>
...
</Discover>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Discover</a> , <a href="#">Execute</a>
Child elements	<a href="#">PropertyList</a>

# Remarks

The **Properties** element represents XMLA properties used to control aspects of the **Discover** and **Execute** methods, such as defining the information required to connect to the data source, specifying the return format of the result set, or specifying the locale in which the data should be formatted.

The available properties and their values can be obtained by using the **DISCOVER\_PROPERTIES** request type with the **Discover** method.

## Example

XML

```
<Properties>
 <PropertyList>
 <DataSourceInfo>
 Provider=MSOLAP;Data Source=local;
 </DataSourceInfo>
 <Catalog>
 Foodmart 2000
 </Catalog>
 <Format>
 Multidimensional
 </Format>
 </PropertyList>
</Properties>
```

# PropertyList Element - Supported XMLA Properties

Article • 12/09/2022

Analysis Services supports the properties listed in the following table. You use these listed properties in the [Properties](#) element of the [Discover](#) and [Execute](#) methods.

[Expand table](#)

Name	Description	Type	Values
AxisFormat	<p>Determines the format used within an <a href="#">MDDataSet</a> result set to describe the axes of the multidimensional dataset. This property can have the values listed in the following table.</p> <p>This property can be used with the <a href="#">Execute</a> method.</p>	Optional, write-only <b>String</b> property	<p><i>ClusterFormat</i>: The <a href="#">MDDataSet</a> axis is made up of one or more <a href="#">CrossProduct</a> elements.</p> <p><i>CustomFormat</i>: Analysis Services uses the <a href="#">TupleFormat</a> format setting.</p> <p><i>TupleFormat</i> Default. The <a href="#">MDDataSet</a> axis contains one or more <a href="#">Tuple</a> elements.</p>
BeginRange	<p>Contains a zero-based integer value corresponding to a <a href="#">CellOrdinal</a> attribute value. (The <a href="#">CellOrdinal</a> attribute is part of the <a href="#">Cell</a> element in the <a href="#">CellData</a> section of <a href="#">MDDataSet</a>.)</p> <p>The default value for this property is -1.</p> <p>This property can be used with the <a href="#">Execute</a> method.</p> <p>Used together with the <a href="#">EndRange</a> property, the client application can use this property to restrict an OLAP dataset returned by a command to a specific range of cells. If -1 is specified, all cells up to the cell specified in the <a href="#">EndRange</a> property are returned.</p>	Optional, write-only <b>Integer</b> property	
Catalog	<p>When establishing a session with an Analysis Services instance to send an XMLA command, this property is equivalent to the OLE DB property, <a href="#">DBPROP_INIT_CATALOG</a>.</p> <p>When you set this property during a session to change the current database for the session, this property is equivalent to the OLE DB property, <a href="#">DBPROP_CURRENTCATALOG</a>.</p> <p>The default value for this property is an empty string.</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, read/write <b>String</b> property	
CatalogLocation	<p>This property is equivalent to the OLE DB property, <a href="#">DBPROP_CATALOGLOCATION</a>.</p> <p>The default value for this property is zero (0), equivalent to <a href="#">DBPROPVAL_CL_START</a>.</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, read-only <b>Integer</b> property	
ClientProcessID	<p>Contains the identifier (ID) of the process thread for the current session.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, read/write <b>Integer</b> property	
CommitTimeout	Determines how long, in milliseconds, the commit phase of a currently running XMLA command	Optional, write-only	

Name	Description	Type	Values
	<p>waits before rolling back. When greater than 0, overrides the value of the corresponding CommitTimeout property in the server configuration. The commit phase corresponds to XMLA commands such as <a href="#">Statement</a> or <a href="#">Process</a>.</p> <p>A value of zero (0) indicates that the instance waits indefinitely.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Integer property	
Content	<p>Determines the type of data that is returned from the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, write-only <b>String</b> property	<i>SchemaData</i> : Default. Returns the schema info and the data. <i>None</i> : Allows the structure of the command to be verified, but not run.  <i>Schema</i> : Returns the XML schema that relates to the requested command. The XML schema indicates columns and other information.  <i>Data</i> : Returns only the data that was requested.
Cube	<p>Contains the name of the cube that sets the context for the command. If the command itself contains a cube name, such as within the FROM clause of a Multidimensional Expressions (MDX) SELECT statement, the setting of this property is ignored.</p> <p>The default value for this property is an empty string.</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, write-only <b>String</b> property	
DataSourceInfo	<p>Contains the information, such as the instance name, required to connect to the data source.</p> <p>Client applications should not construct the contents of the <b>DataSourceInfo</b> property to send to an instance. Instead, the client application should find the data sources supported by the provider by using the <a href="#">Discover</a> method to retrieve the DISCOVER_DATASOURCES rowset. The client application then sends back the same value for the <b>DataSourceInfo</b> property that the client retrieved from the DISCOVER_DATASOURCES rowset.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Required, read/write <b>String</b> property	
DbpropCatalogTerm	<p>This property is equivalent to the OLE DB property, DBPROP_CATALOGTERM.</p> <p>The default value for this property is "Database".</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, read-only <b>String</b> property	
DbpropCatalogUsage	<p>This property is equivalent to the OLE DB property, DBPROP_CATALOGUSAGE.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <a href="#">Discover</a> and <a href="#">Execute</a> methods.</p>	Optional, read-only <b>Integer</b> property	

Name	Description	Type	Values
DbpropColumnDefinition	<p>This property is equivalent to the OLE DB property, DBPROP_COLUMNDEFINITION.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropConcatNullBehavior	<p>This property is equivalent to the OLE DB property, DBPROP_CONCATNULLBEHAVIOR.</p> <p>The default value for this property is 1, equivalent to DBPROPVAL_CB_NULL.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropDataSourceReadOnly	<p>This property is equivalent to the OLE DB property, DBPROP_DATASOURCEREADONLY.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Boolean property	
DbpropGroupBy	<p>This property is equivalent to the OLE DB property, DBPROP_GROUPBY.</p> <p>The default value for this property is 2, equivalent to DBPROPVAL_GB_EQUALS_SELECT.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropHeterogeneousTables	<p>This property is equivalent to the OLE DB property, DBPROP_HETEROGENEOUSTABLES.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropIdentifierCase	<p>This property is equivalent to the OLE DB property, DBPROP_IDENTIFIERCASE.</p> <p>The default value for this property is 8, equivalent to DBPROPVAL_IC_MIXED.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropInitMode	<p>This property is equivalent to the OLE DB property, DBPROP_INIT_MODE.</p> <p>The only supported values for this property are DB_MODE_READWRITE and DB_MODE_READ.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
DbpropMaxIndexSize	<p>This property is equivalent to the OLE DB property, DBPROP_MAXINDEXSIZE.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	

Name	Description	Type	Values
DbpropMaxOpenChapters	<p>This property is equivalent to the OLE DB property, DBPROP_MAXOPENCHAPTERS.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropMaxRowSize	<p>This property is equivalent to the OLE DB property, DBPROP_MAXROWSIZE.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropMaxRowSizeIncludeBlob	<p>This property is equivalent to the OLE DB property, DBPROP_MAXROWSIZEINCLUDESBLOB.</p> <p>The default value for this property is TRUE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional read-only Boolean property	
DbpropMaxTablesInSelect	<p>This property is equivalent to the OLE DB property DBPROP_MAXTABLESINSELECT.</p> <p>The default value for this property is 1.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropMsmdAutoexists	<p>Determines the behavior of autoexists. This property can have the values listed in the following table.</p> <p>Zero or empty are the default values for this property.</p> <p>This is a session property that can only be set when the session is created.</p>	Optional, read/write Integer property	<p>0: Default value, same as 1.</p> <p>1: Apply deep autoexists for query axes and named sets from autoexists. Includes WHERE clauses and subselects.</p> <p>2: Apply deep autoexists for query axes and empty named sets from autoexists. Includes WHERE clause and subselects.</p> <p>3: Apply no autoexists for named sets with WHERE clause. Apply shallow autoexists for query axes WHERE clause. Apply deep autoexists for query with subselects and named sets with subselect</p>
DbpropMsmdCacheMode	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
DbpropMsmdCachePolicy	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
DbpropMsmdCacheRatio	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
DbpropMsmdCacheRatio2	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Double property	

Name	Description	Type	Values
DbpropMsmdCompareCaseNotSensitiveStringFlags	<p>Determines case-sensitive string comparison and sort order functionality. This property controls how comparisons are made in character sets that do not support uppercase and lowercase characters, such as katakana for Japanese and Hindi. The value of this property is set in the first connection of the process thread, and affects all subsequent connections in that process thread.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional read/write <b>Integer</b> property	<p>Use the following <b>Name: Value</b> pairs to determine flags to use:</p> <p><b>NORM_IGNORECASE</b>: 0x00000001. Case is ignored.</p> <p>Not applicable: 0x00000002. Binary comparison. Characters are compared based on their underlying value in the character set, not on their order in the particular alphabet.</p> <p><b>NORM_IGNORENONSPACE</b>: 0x00000010. Nonspacing characters are ignored.</p> <p><b>NORM_IGNORESYMBOLS</b>: 0x00000100. Symbols are ignored.</p> <p><b>NORM_IGNOREKANATYPE</b>: 0x00001000. No differentiation is made between hiragana and katakana characters. When compared, corresponding hiragana and katakana characters are considered to be equal.</p> <p><b>NORM_IGNOREWIDTH</b>: 0x00010000. No differentiation is made between single-byte and double-byte versions of the same character.</p> <p><b>SORT_STRINGSORT</b>: 0x00100000. Punctuation is treated the same as symbols.</p>
DbpropMsmdCompareCaseSensitiveStringFlags	<p>Determines case-insensitive string comparison and sort order functionality. This property controls how comparisons are made in character sets that do not support uppercase and lowercase characters, such as katakana for Japanese and Hindi. The value of this property is set in the first connection of the process thread, and affects all subsequent connections in that process thread.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write <b>Integer</b> property	<p>Use the following <b>Name: Value</b> pairs to determine flags to use:</p> <p><b>NORM_IGNORECASE</b>: 0x00000001. Case is ignored.</p> <p>Not applicable: 0x00000002. Binary comparison. Characters are compared based on their underlying value in the character set, not on their order in the particular alphabet.</p> <p><b>NORM_IGNORENONSPACE</b>: 0x00000010. Nonspacing characters are ignored.</p> <p><b>NORM_IGNORESYMBOLS</b>: 0x00000100. Symbols are ignored.</p> <p><b>NORM_IGNOREKANATYPE</b>: 0x00001000. No differentiation is made between hiragana and katakana characters. When compared, corresponding hiragana and katakana characters are considered equal.</p> <p><b>NORM_IGNOREWIDTH</b>: 0x00010000. No differentiation is made between single-byte and double-byte versions of the same character.</p> <p><b>SORT_STRINGSORT</b>: 0x00100000. Punctuation is treated the same as symbols.</p>
DbpropMsmdDebugMode	<p><i>Usage</i> Optional, read/write <b>String</b> property</p> <p><i>Description</i> Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		

Name	Description	Type	Values
DbpropMsmdDynamicDebugLimit	<p><i>Usage</i> Optional, read/write <b>Integer</b> property</p> <p><i>Description</i> Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropMsmdFlattened2	<p><i>Usage</i> Optional, read/write <b>Boolean</b> property</p> <p><i>Description</i> Outputs all members of a parent-child hierarchy in a single table column in the flattened result, unless the parent-child hierarchy is requested on Axis 0. The Level template for output columns is not used.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropMsmdMDXCompatibility	<p><i>Usage</i> Optional, read/write <b>Integer</b> property</p> <p><i>Description</i> Determines how placeholder members in a ragged or unbalanced hierarchy are treated. This property can have the following values:</p> <p><b>0</b> For compatibility with earlier versions of Analysis Services, this value is equivalent to 1</p> <p><b>1</b> Hierarchies in role-playing dimensions receive a caption that includes the dimension name and the hierarchy name. The caption has the following format: {Dimension}.[Hierarchy] Placeholder members are exposed.</p> <p><b>2</b> Hierarchies in role-playing dimensions receive a caption that includes the dimension name and the hierarchy name. The caption has the following format: [Dimension].[Hierarchy] Placeholder members are not exposed.</p> <p><b>3</b> (Default) Placeholder members are not exposed.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropMsmdMDXUniqueNameStyle	<p><i>Usage</i> Optional, read/write <b>Integer</b> property</p> <p><i>Description</i> Determines the algorithm for generating the unique names of members in a dimension. This property can have the values listed in the following table.</p>		

Name	Description	Type	Values
	<p><b>0</b></p> <p>For compatibility with earlier versions of Analysis Services, this value is equivalent to 2.</p>		
	<p><b>1</b></p> <p>Uses a key path algorithm: <code>[dim].&amp;[key1].&amp;[key2]</code></p>		
	<p><b>2</b></p> <p>Uses a name path algorithm: <code>[dim].[name1].&amp;[name2]</code></p>		
	<p><b>3</b></p> <p>Uses guaranteed unique names that are stable over time.</p> <p>The default value for this property is 6.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropMsmdSQLCompatibility	<p>Reserved for future use.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
DbpropMsmdSubQueries	<p>A bitmask that determines the behavior of subqueries.</p> <p>Zero or empty are the default values for this property.</p> <p>This is a session property that can only be set when the session is created.</p> <p>See <a href="#">Calculated Members in Subselects and Subcubes</a> for a detailed explanation of the behavior of calculated members or calculated sets in subselects and subcubes.</p>	Optional, read/write Integer property	<p>This property can have one of the following values:</p> <ul style="list-style-type: none"> <li>0: Default value, Compatible with earlier versions of Analysis Services. Calculated members or calculated sets are not allowed in subselects or subcubes..</li> <li>1: Calculated members or calculated sets are allowed in subselects or subcubes. Ascendants of the calculated member are not included in the space of the subselect or subcube.</li> <li>2: Calculated members or calculated sets are allowed in subselects or subcubes. Ascendants of the calculated member are included in the space of the subselect or subcube.</li> </ul>
DbpropMsmdUseFormulaCache	<p><i>Usage</i></p> <p><i>Description</i></p> <p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropMultiTableUpdate	<p><i>Usage</i></p> <p>Optional, read-only <b>Boolean</b> property</p> <p><i>Description</i></p> <p>This property is equivalent to the OLE DB property, DBPROP_MULTITABLEUPDATE.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropNullCollation	<p><i>Usage</i></p> <p>Optional, read-only <b>Integer</b> property</p> <p><i>Description</i></p>		

Name	Description	Type	Values
	<p>This property is equivalent to the OLE DB property, DBPROP_NULLCOLLATION.</p> <p>The default value for this property is 4, equivalent to DBPROPVAL_NC_LOW.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
DbpropOrderByColumnsInSelect	<p>This property is equivalent to the OLE DB property, DBPROP_ORDERBYCOLUMNSINSELECT.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Boolean property	
DbpropOutputParameterAvailable	<p>This property is equivalent to the OLE DB property, DBPROP_OUTPUTPARAMETERAVAILABILITY.</p> <p>The default value for this property is 1, equivalent to DBPROPVAL_OA_NOTSUPPORTED.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropPersistentIdType	<p>This property is equivalent to the OLE DB property, DBPROP_PERSISTENTIDTYPE.</p> <p>The default value for this property is 4, equivalent to DBPROPVAL_PT_NAME.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropPrepareAbortBehavior	<p>This property is equivalent to the OLE DB property, DBPROP_PREPAREABORTBEHAVIOR.</p> <p>The default value for this property is 1, equivalent to DBPROPVAL_CB_DELETE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropPrepareCommitBehavior	<p>This property is equivalent to the OLE DB property DBPROP_PREPARECOMMITBEHAVIOR.</p> <p>The default value for this property is 1, equivalent to DBPROPVAL_CB_DELETE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropProcedureTerm	<p>This property is equivalent to the OLE DB property, DBPROP_PROCEDURETERM.</p> <p>The default value for this property is "Calculated member".</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only String property	
DbpropQuotedIdentifierCase	<p>This property is equivalent to the OLE DB property, DBPROP_QUOTEDIDENTIFIERCASE.</p> <p>The default value for this property is 8, equivalent to DBPROPVAL_IC_MIXED.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional read-only Integer property	
DbpropSchemaUsage	<p>This property is equivalent to the OLE DB property, DBPROP_SCHEMAUSAGE.</p>	Optional, read-only	

Name	Description	Type	Values
	<p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Integer property	
DbpropSqlSupport	<p>This property is equivalent to the OLE DB property, DBPROP_SQLSUPPORT.</p> <p>The default value for this property is 512, equivalent to DBPROPVAL_SQL_SUBMINIMUM.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropSubqueries	<p>This property is equivalent to the OLE DB property, DBPROP_SUBQUERIES.</p> <p>Note: While Data Mining Extensions (DMX) supports subqueries, this property refers to subquery support in SQL.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropSupportedTxnDdl	<p>This property is equivalent to the OLE DB property, DBPROP_SUPPORTEDTXNDDL.</p> <p>The default value for this property is zero (0), equivalent to DBPROPVAL_TC_NONE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropSupportedTxnIsoLevels	<p>This property is equivalent to the OLE DB property, DBPROP_SUPPORTEDTXNISOLEVELS.</p> <p>The default value for this property is 4096, equivalent to DBPROPVAL_TI_READCOMMITTED.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropSupportedTxnIsoRetain	<p>This property is equivalent to the OLE DB property, DBPROP_SUPPORTEDTXNISORETAIN.</p> <p>The default value for this property is 292, equivalent to a combination of DBPROPVAL_TR_ABORT_NO, DBPROPVAL_TR_COMMIT_NO, and DBPROPVAL_TR_NONE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
DbpropTableTerm	<p><b>Usage</b> Optional, read-only String property</p> <p><b>Description</b> This property is equivalent to the OLE DB property, DBPROP_TABLETERM.</p> <p>The default value for this property is "Cube".</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
Dialect	<p>You can use the <b>Dialect</b> property when you expect that most of queries will use one particular dialect over any other.</p> <p>Query syntax can be similar for language dialects,</p>	Optional, read/write String property	<p>The following Name: Value pairs are dialects a this property:</p> <p>DBGUID_SQL: C8B522D7-5CF3-11CE-ADE5-00AA0044773D.</p>

Name	Description	Type	Values
	<p>such as DMX and SQL. Because the syntax can be similar, Analysis Services may not be able to infer the dialect from the query syntax. If a query does not run in one dialect, the Analysis Services instance may try to run the query again in a different dialect.</p> <p>If the <b>Dialect</b> property is set, Analysis Services returns query execution errors in the dialect that has precedence, even if the provider tries to run the query again in another dialect. For example, the <b>Dialect</b> property is set to MDGUID_DM. The provider first tries to run the query as a data mining query, but this query fails. The provider then resubmits the query as an SQL query. However, this SQL query also fails. Because the value of the <b>Dialect</b> property is MDGUID_DM, Analysis Services returns a data mining error message, not an SQL error message.</p> <p>If the <b>Dialect</b> property is not set, Analysis Services returns query execution errors in the dialect last used. For example, the <b>Dialect</b> property is not set, and a data mining query fails. The provider then resubmits the query as SQL. The SQL query also fails. Because the <b>Dialect</b> property is not set, the provider returns an SQL error message instead of a data mining error message.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		<p>parser has precedence.</p> <p><b>MDGUID_DM:</b> 62C58FED-CCA5-44F1-83B6-7B45682B3904. 1 parser has precedence.</p> <p><b>MDGUID_MDX:</b> A07CCCD0-8148-11D0-87BB-00C04FC33942. parser has precedence.</p>
Disable Prefetch Facts	<p>When set to True, the engine stops trying to prefetch values for the length of the session.</p> <p>The default value for this property is <b>False</b>.</p>	Optional, read/write Boolean property	
EffectiveRoles	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only String property	
EffectiveUserName	<p>Specifies the name of an account to use to override the user name when connecting to an Analysis Services instance. The value of the property is not normalized, in that the MDX UserName function returns the literal value if this property is used. This property can only be used by server administrators.</p> <p>This property supports the following SID types: User, Group, Alias, WellKnownGroup, Computer.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only String property	
EndRange	Specifies a zero-based integer value corresponding to a <b>CellOrdinal</b> attribute value. (The <b>CellOrdinal</b> attribute is part of the <b>Cell</b>	Optional, write-only	

Name	Description	Type	Values
	<p>element in the <b>CellData</b> section of <b>MDDDataSet</b>).</p> <p>Used together with the <b>BeginRange</b> property, the client application can use this property to restrict an OLAP dataset returned by a command to a specific range of cells. If -1 is specified, all cells from the cell specified in the <b>BeginRange</b> property are returned.</p> <p>The default value for this property is -1.</p> <p>This property can be used with the <b>Execute</b> method.</p>	Integer property	
ExecutionMode	<p>Reserved for future use.</p> <p>The default value for this property is <i>Execute</i>.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only String property	
ForceCommitTimeout	<p>Determines for how long, in seconds, the commit phase of a currently running XMLA command waits before forcing previously issued commands to roll back. The commit phase corresponds to XMLA commands such as <b>Statement</b> or <b>Process</b>.</p> <p>A value of zero (0) indicates that the instance waits indefinitely.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only Integer property	
Format	<p>Determines the type of result set that is returned from the <b>Discover</b> and <b>Execute</b> methods.</p> <p>The default value for this property is <i>Native</i>.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only String property	<p>This property can have the following values:</p> <p><i>Tabular</i>: Returns a result set using the <b>Rowset</b> data type.</p> <p><i>Multidimensional</i>: Returns a rowset using the <b>MDDDataSet</b> data type.</p> <p><i>Native</i>: No format is explicitly specified. Analysis returns the appropriate format for the comma actual result type is identified by the namespace result.</p>
ImpactAnalysis	<p>Reserved for future use.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only Boolean property	
LocaleIdentifier	<p>Reads or sets the locale identifier (LCID) used by the <b>Discover</b> or <b>Execute</b> method. For the complete hexadecimal list of language identifiers, look for "Language Identifiers" in the MSDN Library.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
MaximumRows	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only Integer property	
MdpropAggregateCellUpdate	This property is equivalent to the OLE DB property, <b>MDPROP_AGGREGATECELL_UPDATE</b> .	Optional, read-only	

Name	Description	Type	Values
	The default value for this property is 4, equivalent to MDPROPVAL_AU_SUPPORTED.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Integer property	
MdpropAxes	This property is equivalent to the OLE DB property, MDPROP_AXES.  The default value for this property is 2147483647.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	
MdpropDrillFunctions	Determines the level of support for drill functions on the server.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	The following values are used to build a valid I  MDPROPVAL_MDF_BASIC (0x01)  MDPROPVAL_MDF_ASYMMETRIC (0x02)  MDPROPVAL_MDF_CALC_MEMBERS (0x04)
MdpropFlatteningSupport	This property is equivalent to the OLE DB property, MDPROP_FLATTENING_SUPPORT.  The default value for this property is 1, equivalent to MDPROPVAL_FS_FULL_SUPPORT.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	The default values are:  3 for SQL Server 2008  7 for SQL Server 2008 R2 and SQL Server 2012
MdpropMdxCaseSupport	This property is equivalent to the OLE DB property, MDPROP_MDX_CASESUPPORT.  The default value for this property is zero (0).  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	
MdpropMdxDescFlags	This property is equivalent to the OLE DB property, MDPROP_MDX_DESCFLAGS.  The default value for this property is 7, equivalent to MDPROPVAL_MD_BEFORE, MDPROPVAL_MD_AFTER, and MDPROPVAL_MD_SELF.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	
MdpropMdxFormulas	This property is equivalent to the OLE DB property MDPROP_MDX_FORMULAS.  The default value for this property is 63, equivalent to a combination of MDPROPVAL_MF_WITH_CALCMEMBERS, MDPROPVAL_MF_WITH_NAMEDSETS, MDPROPVAL_MF_CREATE_CALCMEMBERS, MDPROPVAL_MF_CREATE_NAMEDSETS, MDPROPVAL_MF_SCOPE_SESSION, and MDPROPVAL_MF_SCOPE_GLOBAL.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property	
MdpropMdxJoinCubes	This property is equivalent to the OLE DB property, MDPROP_MDX_JOINCUBES.	Optional, read-only	

Name	Description	Type	Values								
	The default value for this property is 1, equivalent to MDPROPVAL_MJC_SINGLECUBE.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Integer property									
MdpropMdxMemberFunctions	This property is equivalent to the OLE DB property, MDPROP_MDX_MEMBER_FUNCTIONS.  The default value for this property is 15, equivalent to a combination of all available OLE DB values.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property									
MdpropMdxNamedSets	This property is used in creating named sets.	Optional, read-only Integer property	A bitmask from values listed in the following table:  <table> <tr> <td><i>0x01</i></td><td>MDPROPVAL_MNS_BASIC.</td></tr> <tr> <td><i>0x02</i></td><td>MDPROPVAL_MNS_DYNAMIC.</td></tr> <tr> <td><i>0x04</i></td><td>MDPROPVAL_MNS_DISPLAYFOLDER.</td></tr> <tr> <td><i>0x08</i></td><td>MDPROPVAL_MNS_CAPTION.</td></tr> </table> A value of 15 is the default value for this property.	<i>0x01</i>	MDPROPVAL_MNS_BASIC.	<i>0x02</i>	MDPROPVAL_MNS_DYNAMIC.	<i>0x04</i>	MDPROPVAL_MNS_DISPLAYFOLDER.	<i>0x08</i>	MDPROPVAL_MNS_CAPTION.
<i>0x01</i>	MDPROPVAL_MNS_BASIC.										
<i>0x02</i>	MDPROPVAL_MNS_DYNAMIC.										
<i>0x04</i>	MDPROPVAL_MNS_DISPLAYFOLDER.										
<i>0x08</i>	MDPROPVAL_MNS_CAPTION.										
MdpropMdxNonMeasureExpressions	This property is equivalent to the OLE DB property, MDPROP_MDX_NONMEASURE_EXPRESSIONS.  The default value for this property is zero (0), equivalent to MDPROPVAL_NME_ALLDIMENSIONS.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property									
MdpropMdxNumericFunctions	This property is equivalent to the OLE DB property, MDPROP_MDX_NUMERIC_FUNCTIONS.  The default value for this property is 2047, equivalent to a combination of MDPROPVAL_MNF_MEDIAN, MDPROPVAL_MNF_VAR, MDPROPVAL_MNF_STDEV, MDPROPVAL_MNF_RANK, MDPROPVAL_MNF_AGGREGATE, MDPROPVAL_MNF_COVARIANCE, MDPROPVAL_MNF_CORRELATION, MDPROPVAL_MNF_LINREGSLOPE, MDPROPVAL_MNF_LINREGVARIANCE, MDPROPVAL_MNF_LINREG2, and MDPROPVAL_MNF_LINREGPOINT.  This property can be used with the <b>Discover</b> and <b>Execute</b> methods.	Optional, read-only Integer property									
MdpropMdxObjQualification	This property is equivalent to the OLE DB property, MDPROP_MDX_OBJQUALIFICATION.  The default value for this property is 496, equivalent to a combination of MDPROPVAL_MOQ_DIM_HIER,	Optional, read-only Integer property									

Name	Description	Type	Values
	<p>MDPROPVAL_MOQ_DIMHIER_LEVEL, MDPROPVAL_MOQ_DIMHIER_MEMBER, MDPROPVAL_MOQ_LEVEL_MEMBER, and MDPROPVAL_MOQ_MEMBER_MEMBER.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
MdpropMdxOuterReference	<p>This property is equivalent to the OLE DB property MDPROP_MDX_OUTERREFERENCE.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
MdpropMdxQueryByProperty	<p>This property is equivalent to the OLE DB property, MDPROP_MDX_QUERYBYPROPERTY.</p> <p>The default value for this property is TRUE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Boolean property	
MdpropMdxRangeRowset	<p>This property is equivalent to the OLE DB property, MDPROP_MDX_RANGEROWSET.</p> <p>The default value for this property is 4, equivalent to MDPROPVAL_RR_UPDATE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
MdpropMdxSetFunctions	<p>This property is equivalent to the OLE DB property, MDPROP_MDX_SET_FUNCTIONS.</p> <p>The default value for this property is 524287, equivalent to a combination of MDPROPVAL_MSF_TOPPERCENT, MDPROPVAL_MSF_BOTTOMPERCENT, MDPROPVAL_MSF_TOPSUM, MDPROPVAL_MSF_BOTTOMSUM, MDPROPVAL_MSF_PERIODSTODATE, MDPROPVAL_MSF_LASTPERIODS, MDPROPVAL_MSF_YTD, MDPROPVAL_MSF_QTD, MDPROPVAL_MSF_MTD, MDPROPVAL_MSF_WTD, MDPROPVAL_MSF_DRILLDOWNMEMBER, MDPROPVAL_MSF_DRILLDOWNLEVEL, MDPROPVAL_MSF_DRILLDOWNMEMBERTOP, MDPROPVAL_MSF_DRILLDOWNMEMBERBOTTOM, MDPROPVAL_MSF_DRILLDOWNLEVEL, MDPROPVAL_MSF_DRILLDOWNLEVELTOP, MDPROPVAL_MSF_DRILLUPMEMBER, MDPROPVAL_MSF_DRILLUPLEVEL, and MDPROPVAL_MSF_TOGGLEDRILLSTATE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
MdpropMdxSlicer	<p>This property is equivalent to the OLE DB property, MDPROP_MDX_SLICER.</p> <p>The default value for this property is 2, equivalent to MDPROPVAL_MS_SINGLETUPLE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
MdpropMdxStringCompop	<p>This property is equivalent to the OLE DB property, MDPROP_MDX_STRING_COMPOP.</p> <p>The default value for this property is 15, equivalent to a combination of</p>	Optional, read-only Integer property	

Name	Description	Type	Values
	<p>MDPROPVAL_MSC_LESSTHAN, MDPROPVAL_MSC_GREATERTHAN, MDPROPVAL_MSC_LESSTHANEQUAL, and MDPROPVAL_MSC_GREATERTHANEQUAL.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		
MdpropMdxSubQueries	<p>Indicates the level of support for subqueries in MDX.</p> <p>A value of 63 is the default value for this property in SQL Server 2014.</p> <p>A value of 31 is the default value for this property in SQL Server 2008 R2 and SQL Server 2012.</p> <p>A value of 15 is the default value for this property in SQL Server 2008.</p> <p>A value of 3 is the default value for this property in SQL Server 2005 Analysis Services.</p>	Optional, read-only Integer property	<p>Valid values for this property are a bitmask made from the following values:</p> <ul style="list-style-type: none"> <li>0x01: MDPROPVAL_MSQ_BASIC</li> <li>0x02: MDPROPVAL_MSQ_ARBITRARYSHAPE</li> <li>0x04: MDPROPVAL_MSQ_NONVISUAL</li> <li>0x08: MDPROPVAL_MSQ_CALCMEMBERS</li> <li>0x10: MDPROPVAL_MSQ_CALCMEMBERS2</li> </ul>
MdpropNamedLevels	<p>This property is equivalent to the OLE DB property, MDPROP_NAMED_LEVELS.</p> <p>The default value for this property is 3, equivalent to a combination of MDPROPVAL_NL_NAMEDLEVELS and MDPROPVAL_NL_NUMBEREDLEVELS.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
MdxMissingMemberMode	<p>Indicates whether missing members are ignored in MDX statements.</p> <p>This property is equivalent to the OLE DB property, DBPROP_MDX_MISSING_MEMBER_MODE.</p> <p>The default value for this property is <i>Default</i>.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only String property	<p>This property can have one of the following values: <i>Default</i>: Use value generated by the Analysis Services instance. <i>Error</i>: Generate an error. <i>Ignore</i>: Always ignore missing members.</p>
MDXSupport	<p>Specifies an enumeration that describes the degree of MDX support.</p> <p>The default value for this property is <i>Core</i>.</p> <p>This property can be used with the <b>Discover</b> method.</p> <p>Note that currently, the only valid value for this enumeration is <i>Core</i>. Other values may be defined for this enumeration in the future.</p>	Optional, read-only String property	<p>This property can have the following value: <i>Core</i>: All MDX options are supported.</p>
NonEmptyThreshold	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional read/write Integer property	
Password	<p>This property is no longer supported.</p> <p>For backward compatibility, this property is ignored without generating an error when used with the <b>Execute</b> or <b>Discover</b> method.</p>	Optional write-only String property	
ProviderName	This property is equivalent to the OLE DB property, DBPROP_DBMSNAME.	Optional, read-only	

Name	Description	Type	Values
	<p>The default value for this property is "OLAP Server".</p> <p>This property can be used with the <b>Discover</b> method.</p>	String property	
ProviderType	<p>This property is equivalent to the OLE DB property, DBPROP_DATASOURCE_TYPE.</p> <p>The default value for this property is 6.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
ProviderVersion	<p>This property is equivalent to the OLE DB property, DBPROP_DBMSVER.</p> <p>The default value for this property is the version of the Analysis Services instance.</p> <p>This property can be used with the <b>Discover</b> method.</p>	Optional, read-only String property	
ReadOnlySession	<p>Reserved for future use.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
RealTimeOlap	<p>When set to TRUE, indicates that all the partitions listening for table notifications are to be queried in real time, bypassing caching. This property is equivalent to the OLE DB property, DBPROP_MSMD_REAL_TIME OLAP.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Boolean property	
ReturnCellProperties	<p>Specifies whether cell properties will be returned.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Boolean property	
Roles	<p>Specifies a comma-delimited string of the role names under which a client application connects to an Analysis Services instance. This property lets the user connect using a role other than the one he or she is currently using. For example, a server administrator may want to connect to a cube as a member of a role to test permissions granted to that role. This user must be a member of the role specified in order to connect using this property.</p> <p><b>** Important **</b> Role names are case-sensitive, and spaces should not be used between the comma-delimited role names. Otherwise errors and unexpected results may be returned by queries to secured cell sets.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write String property	
SafetyOptions	<p>Determines whether unsafe libraries can be registered and loaded by client applications.</p> <p>The value of this property also determines whether the PASSTHROUGH keyword is allowed in</p>	Optional, read/write Integer property	<p>This property can have one of the values listed following Name: Value pairs:</p> <p>DBPROPVAL_MSMD_SAFETY_OPTIONS_DEF0. This value is treated as</p>

Name	Description	Type	Values
	<p>local cubes. An error occurs in the following situations:</p> <ul style="list-style-type: none"> <li>-If a client application tries to create a local cube with an INSERT INTO statement that contains the PASSTHROUGH keyword.</li> <li>-If a client application tries to update a local cube that contains an INSERT INTO statement which uses the PASSTHROUGH keyword.</li> </ul> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>		<p>DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLOV</p> <p>connections to a local cube, this value depend whether the CREATECUBE connection string p used. If the CREATECUBE connection string pr used, this value is the same as DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLOV</p> <p>Otherwise, this value is the same as DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLOV</p> <p><b>DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLC</b></p> <p>1. This value enables all user-defined function without verifying that they are safe for initialization scripting. For connections to local cubes, this v enables usage of stored procedures and of the PASSTHROUGH keyword in INSERT INTO state</p> <p><b>Security Note **:</b> This option is not recomme</p> <p><b>DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLC</b></p> <p>2. This value makes sure that all classes for a p user-defined function library are checked to m that they are safe for initialization and scriptin connections to local cubes, this value prevents the PASSTHROUGH keyword in INSERT INTO s and of stored procedures where the Permissio property is not set to Safe. This value also rem actions in the MDSHEMA_ACTIONS schema i that have either a value of HTML or COMMON ACTION_TYPE column, or have a value of URL ACTION_TYPE column and a value in the CON column that does not start with "http://" or "h</p> <p><b>DBPROPVAL_MSMD_SAFETY_OPTIONS_ALLO</b></p> <p>3: This value prevents user-defined functions f used during the session. For connections to lo this value prevents usage of all stored procedu of the PASSTHROUGH keyword in INSERT INT statements. This value also removes all actions MDSHEMA_ACTIONS schema rowset.</p>
SecuredCellValue	<p>Specifies the error code and the values for the <b>Value</b> and <b>Formatted Value</b> cell properties to be returned when it tries to access a secured cell.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	<p>Optional, read/write</p> <p><b>Integer</b> property</p>	<p>This property can have one of the following va</p> <p>0: Default. For compatibility with earlier versio value is the same as 1. The meaning of this de is subject to change in future versions.</p> <p>1: Returns HRESULT = NO_ERROR. The Value p the cell contains the result as a variant data ty string "#N/A" is returned in the <b>Formatted Val</b> property.</p> <p>2: Returns an error as the value of HRESULT.</p> <p>3: Returns NULL in both the <b>Value</b> and <b>Format</b> properties.</p> <p>4: Returns a numeric zero (0) in the <b>Value</b> prop returns a formatted zero in the <b>Formatted Val</b> property. For example, 0.00 is returned in the <b>Value</b> property for a cell whose <b>Format</b> propo "#,##".</p> <p>5: Returns the string "#SEC" in both the <b>Value</b> and <b>Formatted Value</b> properties.</p>
ServerName	<p>This property is equivalent to the OLE DB property, DBPROP_SERVERNAME.</p> <p>The default value for this property is the name of the Analysis Services instance.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	<p>Optional, read-only</p> <p><b>String</b> property</p>	

Name	Description	Type	Values
ShowHiddenCubes	<p>Reserved for future use.</p> <p>The default value for this property is FALSE.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Boolean property	
SQLQueryMode	<p>Determines whether calculations are included in SQL queries.</p> <p>The default value for this property is <i>Calculated</i>.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write String property	<p>This property can have one of the following values:</p> <ul style="list-style-type: none"> <li><i>Data</i>: No calculations are included.</li> <li><i>Calculated</i>: Calculations are returned.</li> <li><i>IncludeEmpty</i>: Calculations and empty rows are returned.</li> </ul>
SQLSupport	<p>Specifies the type of SQL support available on the provider.</p> <p>The default value for this property is 512.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
SspropInitAppName	<p>Contains the name of the client application.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write String property	
SspropInitPacketsize	<p>Contains the ID of the client application.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
SspropInitWsid	<p>Contains the ID of the client workstation.</p> <p>There is no default value for this property.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write String property	
StateSupport	<p>Specifies the degree of support for statefulness.</p> <p>The default value for this property is <i>Sessions</i>.</p> <p>This property can be used with the <b>Discover</b> method.</p>	Optional, read-only String property	<p>This property can have one of the following values:</p> <ul style="list-style-type: none"> <li><i>None</i>: Statefulness is not supported.</li> <li><i>Sessions</i>: Statefulness is provided through session support.</li> </ul>
Timeout	<p>Specifies, in seconds, the maximum time that the Analysis Services instance should wait for a request to be successful before returning an error. This property also determines the maximum time that the instance should wait for an update to a writeback table to be successful before returning an error, equivalent to the connection string property, Writeback Timeout.</p> <p>The default value for this property is zero (0).</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read/write Integer property	
TransactionDDL	<p>Reserved for future use.</p> <p>The default value for this property is 0.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, read-only Integer property	
UserName	This property is no longer supported.	Optional, read-only	

Name	Description	Type	Values
	<p>Specifies a string that returns the user name that the Analysis Services instance associates with the command. For backward compatibility, this property is ignored without generating an error when used with the <b>Execute</b> or <b>Discover</b> method. This property is equivalent to the OLE DB property, <code>DBPROP_USERNAME</code>.</p> <p>The default value for this property is the user name that opened the current session or connection.</p> <p>This property can be used with the <b>Execute</b> method.</p>	String property	
VisualMode	<p>This property is equivalent to the OLE DB property, <code>MDPROP_VISUALMODE</code>.</p> <p>The default value for this property is zero (0), equivalent to <code>DBPROPVAL_VISUAL_MODE_DEFAULT</code>.</p> <p>This property can be used with the <b>Discover</b> and <b>Execute</b> methods.</p>	Optional, write-only Integer property

# PropertyList Element (XMLA)

Article • 12/09/2022

Contains a collection of XML for Analysis (XMLA) properties used by the [Discover](#) and [Execute](#) methods.

## Syntax

XML

```
<Properties>
 <PropertyList>
 <!-- Zero or more XMLA properties -->
 </PropertyList>
</Properties>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Properties</a>
Child elements	XMLA properties (see Remarks)

## Remarks

The **PropertyList** element contains a collection of XMLA properties. Each property allows the user to control some aspect of the **Discover** or **Execute** method, such as defining the information required to connect to the data source, specifying the return format of the result set, or specifying the locale in which the data should be formatted. Each XMLA property in the **PropertyList** element is defined by a separate XML element. The value of the XMLA property is the data contained by the XML element, and the name of the XMLA property corresponds to the name of the XML element.

The available properties and their values can be obtained by using the **DISCOVER\_PROPERTIES** request type with the **Discover** method. There is no required order for the properties listed in the **PropertyList** element.

## Example

```
XML

<Properties>
 <PropertyList>
 <DataSourceInfo>
 Provider=MSOLAP;Data Source=local;
 </DataSourceInfo>
 <Catalog>
 Foodmart 2000
 </Catalog>
 <Format>
 Multidimensional
 </Format>
 </PropertyList>
</Properties>
```

# Queries Element (XMLA)

Article • 12/09/2022

Contains a collection of [Query](#) elements used by the [DesignAggregations](#) command during usage-based optimization.

## Syntax

XML

```
<DesignAggregations>
 ...
 <Queries>
 <Query>...</Query>
 </Queries>
 ...
</DesignAggregations>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[] [Expand table](#)

# Query Element (XMLEA)

Article • 12/09/2022

Contains a query within the [Queries](#) collection used by the [DesignAggregations](#) command during usage-based optimization.

## Syntax

XML

```
<Queries>
 ...
 <Query>...</Query>
 ...
</Queries>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Queries</a>
Child elements	None

## Remarks

The **DesignAggregations** command supports usage-based optimization by including one or more **Query** elements in the **Queries** collection of the command. Each **Query** element represents a goal query that the design process uses to define aggregations that target the most frequently used queries. You can either specify your own goal queries, or you can use the information stored by an instance of Analysis Services in the query log to retrieve information about the most frequently used queries.

If you are iteratively designing aggregations, you only have to pass goal queries in the first **DesignAggregations** command because the instance stores these goal queries and uses these queries during subsequent **DesignAggregations** commands. After you pass goal queries in the first **DesignAggregations** command of an iterative process, any subsequent **DesignAggregations** command that contains goal queries in the **Queries** property generates an error.

The **Query** element contains a comma-delimited value that contains the following arguments:

*Frequency, Dataset[ ,Dataset...]*

#### *Frequency*

A weighting factor that corresponds to the number of times that the query has previously been executed. If the **Query** element represents a new query, the *Frequency* value represents the weighting factor used by the design process to evaluate the query. As the frequency value becomes larger, the weight that is put on the query during the design process increases.

#### *Dataset*

A numeric string that specifies which attributes from a dimension are to be included in the query. This string must have the same number of characters as the number of attributes in the dimension. Zero (0) indicates that the attribute in the specified ordinal position is not included in the query for the specified dimension, while one (1) indicates that the attribute in the specified ordinal position is included in the query for the specified dimension.

For example, the string "011" would refer to a query involving a dimension with three attributes, from which the second and third attributes are included in the query.

#### Note

Some attributes are excluded from consideration in the dataset.

Each dimension in the measure group that contains the aggregation design is represented by a *Dataset* value in the **Query** element. The order of *Dataset* values must

match the order of dimensions included in the measure group.

# ReadWriteMode Element

Article • 12/09/2022

The **ReadWriteMode** database property specifies whether the database is in **ReadWrite** mode or in **ReadOnly** mode. These are the only two possible values of the property.

## Syntax

XML

```
<Database>
...
<ddlns_100_0:ReadWriteMode>...</ddlns_100_0:ReadWriteMode>
...
</Database>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	ReadWrite
Cardinality	0-1: Optional element that can occur more than once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	None

## Remarks

Databases are created in **ReadWrite** mode only. Databases cannot be created in **ReadOnly** mode.

The value of the **ReadWriteMode** element is limited to one of the strings listed in the following table.

[] [Expand table](#)

Value	Description
<i>ReadOnly</i>	No changes or updates can be applied to the database.
<i>ReadWrite</i>	Changes and updates can be applied to the database.

# RequestType Element (XMLA)

Article • 12/09/2022

Determines the type of metadata returned by the [Discover](#) method.

## Syntax

XML

```
<Discover>
 ...
 <RequestType>...</RequestType>
 ...
</Discover>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Discover</a>
Child elements	None

## Remarks

The **RequestType** element determines the schema rowset from which the **Discover** method returns data. This enumeration is limited to the names of the schema rowsets supported by Analysis Services.

 **Note**

The **RequestType** element enumerates only schema rowset names. An error occurs if the schema rowset GUID is used.

 No

# RestrictionList Element (XMLA)

Article • 12/09/2022

Contains a collection of restriction columns and values used by the [Discover](#) method.

## Syntax

XML

```
<Restrictions>
 <RestrictionList>
 <!-- Zero or more restriction columns and values -->
 </RestrictionList>
</Restrictions>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Restrictions</a>
Child elements	Restriction columns and values (see Remarks).

## Remarks

The **RestrictionList** element contains a collection of restriction columns on which the data returned by the **Discover** method can be filtered. Each restriction column in the **RestrictionList** element is defined by a separate XML element. The value of the restriction column is the data contained by the XML element, and the name of the restriction column corresponds to the name of the XML element.

# Restrictions Element (XMLA)

Article • 12/09/2022

Contains restriction columns and data used by the [Discover](#) method.

## Syntax

XML

```
<Discover>
...
<Restrictions>
 <RestrictionList>...</RestrictionList>
</Restrictions>
...
</Discover>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Discover</a>
Child elements	<a href="#">RestrictionList</a>

## Remarks

The **Restrictions** element represents restriction columns and data used to restrict the information retrieved by the **Discover** method.

## Example

XML

```
<Discover xmlns="urn:schemas-microsoft-com:xml-analysis">
 <RequestType>DISCOVER_PROPERTIES</RequestType>
 <Restrictions>
 <RestrictionList xmlns="urn:schemas-microsoft-com:xml-analysis">
 <PropertyName>Catalog</PropertyName>
 </RestrictionList>
 </Restrictions>

# results Element (XMLA)

Article • 12/09/2022

Contains a collection of [root](#) elements returned by the [Execute](#) method using the [Batch](#) command.

**Namespace** `http://schemas.microsoft.com/analysisservices/2003/xmla-multipleresults`

## Syntax

XML

```
<return>
 <results>
 <root>...</root>
 </results>
</return>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">return</a>
Child elements	<a href="#">root</a>

## Remarks

If a **Batch** command is executed by the **Execute** method, the **return** element contains a single **results** element instead of a single **root** element. The content of the **results** element depends on the settings used to run the **Batch** command.

For non-transactional **Batch** commands, the **results** element contains one **root** element for each command executed by the **Batch** command, whether the command completes successfully or unsuccessfully. For transactional **Batch** commands, the **results** element contains only one **root** element, which contains the error information for the command that failed within the **Batch** command.

 No

# return Element (XMLA)

Article • 12/09/2022

Contains information returned by a [DiscoverResponse](#) element in response to a [Discover](#) method call or an [ExecuteResponse](#) element in response to an [Execute](#) method call.

## Syntax

XML
<pre>&lt;DiscoverResponse&gt; &lt;!-- or ExecuteResponse --&gt;   &lt;return&gt;     &lt;root&gt;...&lt;/root&gt;     &lt;!-- or --&gt;     &lt;results&gt;...&lt;/results&gt; &lt;!-- ExecuteResponse only --&gt;   &lt;/return&gt; &lt;/DiscoverResponse&gt;</pre>

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DiscoverResponse</a> , <a href="#">ExecuteResponse</a>
Child elements	See the table below.

Ancestor	Child elements
DiscoverResponse	root
ExecuteResponse	root or results

## Remarks

The **return** element contains the data returned by the **Discover** and **Execute** methods. Typically, the **return** element contains a single **root** element that contains either the data returned by a successful **Discover** or **Execute** method call or an XML for Analysis (XMLA) exception returned by an unsuccessful method call. If the **Execute** method contains a **Batch** command that performs multiple operations, the **return** element contains a **results** element which, in turn, contains one **root** element for each command executed successfully or unsuccessfully by the **Batch** command.

# root Element (XMLA)

Article • 12/09/2022

Contains a result returned by the [Discover](#) method or an XML for Analysis (XMLA) command executed using the [Execute](#) method.

## Syntax

```
XML

<return> <!-- or results-->
 ...
 <root xmlns="urn:schemas-microsoft-com:xml-analysis:mddataset">...</root>
 <!-- for Execute method only -->
 <!-- or -->
 <root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">...</root>
 <!-- or -->
 <root xmlns= xmlns="urn:schemas-microsoft-com:xml-analysis:empty">...
</root>
 ...
</return>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	1-n: Required element that can occur more than once.

[+] Expand table

Ancestor	Data type
DiscoverResponse	Rowset, olapxml_EmptyResult
ExecuteResponse	MDDDataSet, Rowset, olapxml_EmptyResult

# Element relationships

 Expand table

Relationship	Element
Parent elements	<a href="#">results, return</a>
Child elements	None

## Remarks

The **root** element contains the information returned in either the [DiscoverResponse](#) element returned by a single [Discover](#) method call, or in the [ExecuteResponse](#) element returned by a single XMLA command executed by a single [Execute](#) method call.

# row Element (XMLA)

Article • 12/09/2022

Contains a single row of data for a [root](#) element that contains tabular data returned by a [Discover](#) or [Execute](#) method call.

## Syntax

XML

```
<root xmlns="urn:schemas-microsoft-com:xml-analysis:rowset">
 <row>
 <!-- One or more column elements -->
 </row>
</root>
```

## Element characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">root</a> (using the <a href="#">Rowset</a> data type)
Child elements	One or more column elements.

## Remarks

Each row returned by a **root** element that contains tabular data has a corresponding **row** element. Each column in the **root** element is represented by a separate XML element. The value of the column for the **row** element is the data contained by the XML element, and the name of the column corresponds to the name of the XML element.

There are two ways to express a null value for a column within a row:

- A missing column element implies that the column is null.
- The column element may use the `xsi:nil='true'` attribute to indicate that it has a null value.

For example, if a row has a single column called, `Store_Name`, and its value is `NONE`, it can be represented as either:

XML

```
<row>
</row>
```

Or:

XML

```
<row>
 <Store_name xsi:nil='true' />
</row>
```

If a column element contains an error, an **Error** element provides information about an error, as described in the following example:

XML

```
<row> <Store_name>
 <Error xmlns="urn:schemas-microsoft-com:xml-analysis:exception">
 <ErrorCode>3238658054</ErrorCode>
 <Description>The object [X] was not found in the cube when [X] was
parsed.</Description>
 </Error>
 </Store_name>
</row>
```

# Security Element (XMLA)

Article • 12/09/2022

Specifies how to back up or restore security definitions, such as roles and permissions, during a Backup or Restore command.

## Syntax

XML

```
<Backup> <!-- or Restore -->
...
<Security>...</Security>
...
</Backup>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>SkipMembership</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Backup</a> , <a href="#">Restore</a>
Child elements	None

## Remarks

The **Security** element determines whether the security definitions, such as roles and permissions, defined on a Analysis Services database are backed up or restored during, respectively, a **Backup** or **Restore** command. This element also determines if the Windows user accounts and groups defined as members of the security definitions are included as part of the **Backup** or **Restore** command.

The value of this element is limited to one of the strings listed in the following table.

 Expand table

Value	Description
<i>SkipMembership</i>	Include security definitions, but exclude membership information, during <b>Backup</b> or <b>Restore</b> commands.
<i>CopyAll</i>	Include security definitions and membership information during <b>Backup</b> or <b>Restore</b> commands.
<i>IgnoreSecurity</i>	Exclude security definitions during <b>Backup</b> or <b>Restore</b> commands.

# Source Element (Synchronize) (XMLEA)

Article • 12/09/2022

Represents a source database from which to synchronize a target database during a [Synchronize](#) command.

## Syntax

XML

```
<Synchronize>
 <Source>
 <Object>...</Object>
 <ConnectionString>...</ConnectionString>
 </Source>
</Synchronize>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Synchronize</a>
Child elements	<a href="#">ConnectionString</a> , <a href="#">Object</a>

## Remarks

The **Synchronize** command uses the **Source** element to establish a connection to and identify a database on an instance of Analysis Services with which to synchronize the target database.

# Source Element (XMLA)

Article • 12/09/2022

Represents a source partition to be merged during a [MergePartitions](#) command.

## Syntax

XML

```
<Sources>
 <Source>
 <DatabaseID>...</DatabaseID>
 <CubeID>...</CubeID>
 <MeasureGroupID>...</MeasureGroupID>
 <PartitionID>...</PartitionID>
 </Source>
</Sources>
```

## Element characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-n: Required element that can occur more than once.

## Element relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Sources</a>
Child elements	<a href="#">CubeID</a> , <a href="#">DatabaseID</a> , <a href="#">MeasureGroupID</a> , <a href="#">PartitionID</a>

# Remarks

The **Source** element is an object reference to a single partition to be merged into a target partition specified by the **Target** element of the parent **MergePartitions** element.

## Example

The following example combines all four partitions of the `Internet_Sales` measure group into the `Internet_Sales_2004` target partition. The example refers to the **Adventure Works** cube of the sample database.

```
XML

<MergePartitions
 xmlns="http://schemas.microsoft.com/analysisservices/2003/engine">
 <Sources>
 <Source> <DatabaseID>Adventure Works DW Multidimensional
 2012</DatabaseID> <CubeID>Adventure Works</CubeID>
 <MeasureGroupID>Fact Internet Sales 1</MeasureGroupID>
 <PartitionID>Internet_Sales_2001</PartitionID> </Source> <Source>
 <DatabaseID>Adventure Works DW Multidimensional 2012</DatabaseID>

# Tuple Element (XMLA)

Article • 12/09/2022

Contains a collection of [Member](#) elements contained by the parent [Tuples](#) element.

## Syntax

XML

```
<Tuples>
 <Tuple>
 <Member>...</Member>
 </Tuple>
 ...
</Tuples>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Tuples</a>
Child elements	<a href="#">Member</a>

## Remarks

When a client application sets the **AxisFormat** property to *TupleFormat*, an axis is represented as a set of tuples. Each **Axis** element contains a **Tuples** element representing the set of tuples on that axis. Each tuple is represented by using a **Tuple** element that contains **Member** elements from every hierarchy on the axis.

## Example

The following example illustrates the structure of the **Tuple** element when a client specifies *TupleFormat* or *CustomFormat* for the **AxisFormat** XMLA property, given the following members for the axis:

Time hierarchy, 1999, 1999, 2000

Category hierarchy, Actual, Budget, Budget

XML

```
<Axes>
 <Axis name="Axis0">
 <Tuples>
 <Tuple>

# Type Element (XMLA)

Article • 12/09/2022

Determines the type of processing to be performed by the [Process](#) element.

## Syntax

XML

```
<Process>
...
<Type>...</Type>
...
</Process>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Process</a>
Child elements	None

## Remarks

The value of the **Type** element is limited to one of the strings listed in the following table.

[Expand table](#)

Value	Description
<i>ProcessFull</i>	Drops all data in the affected object, and then processes the affected object.
<i>ProcessAdd</i>	Adds new data to the affected object.
<i>ProcessUpdate</i>	Refreshes the data in the affected object.
<i>ProcessIndexes</i>	Creates or rebuilds indexes and aggregations in the affected object.
<i>ProcessScriptCache</i>	If the cube is processed, the server will rebuild the MDX script cache. If not, an error will be raised.  <b>Note</b> Applies only to cube.
<i>ProcessData</i>	Processes data only in the affected object.
<i>ProcessDefault</i>	Detects the state of the affected object and then performs the appropriate processing option on the affected object to fully optimize it and return it to a fully processed state.
<i>ProcessClear</i>	Drops the data in the affected object and all related objects.
<i>ProcessStructure</i>	Processes the structure only of the affected object.
<i>ProcessClearStructureOnly</i>	Clears data only from the affected object.

# UName Element (XMLA)

Article • 12/09/2022

Contains the unique name of the parent [HierarchyInfo](#) or [Member](#) element.

## Syntax

XML

```
<HierarchyInfo> <!-- or Member -->
 ...
 <UName>...</UName>
 ...
</HierarchyInfo>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">HierarchyInfo</a> , <a href="#">Member</a>
Child elements	None

## Remarks

For **HierarchyInfo** elements, the **UName** element contains the name of the property that provides the unique member names of the hierarchy. The value is equivalent to the MEMBER\_UNIQUE\_NAME property defined for axis rowsets in the OLE DB for OLAP specification.

For **Member** elements, the **UName** element contains the unique name of the parent **Member** element.

---

 No

# UnaryOperator Element (XMLA)

Article • 12/09/2022

Contains the unary operator for an attribute member represented by the parent [Attribute](#) element.

## Syntax

XML

```
<Attribute>
 ...
 <UnaryOperator>...</UnaryOperator>
 ...
</Attribute>
```

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attribute</a>
Child elements	None

## Remarks

The **UnaryOperator** element contains a Multidimensional Expressions (MDX) expression that defines the unary operator for the attribute member defined by the parent **Attribute** element.

---

## Feedback

Was this page helpful?

Yes

No

# Value Element (Parameter) (XMLA)

Article • 12/09/2022

Contains the value of a parameter represented by the [Parameter](#) element.

## Syntax

XML

```
<Parameter>
 ...
 <Value>...</Value>
 ...
</Parameter>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	Any
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Parameter</a>
Child elements	None

## Remarks

The **Value** element can store any simple XML type, as well as the XML for Analysis (XMLA) **Rowset** data type, for parameters used by XMLA commands in the [Execute](#) method.

---

## Feedback

Was this page helpful?

Yes

No

# Value Element (XMLEA)

Article • 12/09/2022

Contains the desired value of an [Attribute](#) element to be added by an [Insert](#) command, or a [Cell](#) element to be updated by an [UpdateCells](#) command.

## Syntax

XML
<pre>&lt;Attribute&gt; &lt;!-- or Cell --!&gt; ... &lt;Value&gt;...&lt;/Value&gt; ... &lt;/Attribute&gt;</pre>

## Element characteristics

[+] Expand table

Characteristic	Description
Data type and length	Any
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Attribute</a> , <a href="#">Cell</a>
Child elements	None

## Remarks

For **Attribute** elements, the **Value** element contains the desired value that the member should contain after the **Insert** command is committed.

For **Cell** elements, the **Value** element contains the desired value that the cell should contain after the **UpdateCells** command is committed. The actual value stored in the writeback table for that cell is the difference between the original value of the cell and the desired value of the cell.

The data type used by this element should match the data type of the cell to be updated.

# Warning Element (XMLA)

Article • 12/09/2022

Contains information about a warning returned by an instance of Analysis Services.

## Syntax

XML

```
<Message>
 <Warning
 ErrorCode="unsignedint"
 Severity="string"
 Description="string"
 Source="string"
 HelpFile="string"
 />
</Message>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Message</a>
Child elements	None

# Attributes

 [Expand table](#)

Attribute	Description
ErrorCode	Required <b>UnsignedInt</b> attribute. Contains the numeric return code of the warning.
Severity	Optional <b>String</b> attribute. Contains the severity of the warning.
Description	Optional <b>String</b> attribute. Contains the descriptive text of the warning.
Source	Optional <b>String</b> attribute. Contains the name of the component that generated the warning.
HelpFile	Optional <b>String</b> attribute. Contains the path or URL to the Help file or topic that describes the warning.

## Remarks

# Where Element (XMLEA)

Article • 12/09/2022

Defines a filter condition used by the parent [Drop](#) or [Update](#) command.

## Syntax

XML

```
<Drop> <!-- or Update -->
...
<Where>
 <Attributes>...</Attributes>
</Where>
...
</Insert>
```

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Drop</a> , <a href="#">Update</a>
Child elements	<a href="#">Attributes</a>

## Remarks

For **Drop** commands, the **Where** element, combined with the [DeleteWithDescendants](#) element, identifies the scope of attribute members to be dropped.

For **Update** commands, the **Where** element identifies the scope of attribute members to be updated. Multiple attribute members can be updated by using a combination of attributes included in the **Attributes** collection of the parent **Update** command and the **Attributes** collection of the **Where** element.

# WritebackTableCreation Element (XMLA)

Article • 12/09/2022

Determines whether a writeback table is created during the [Process](#) operation.

## Syntax

```
XML

<Process>
...
 <WritebackTableCreation>...</WritebackTableCreation>
...
</Process>
```

## Element characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Process</a>
Child elements	None

## Remarks

The value of the **WritebackTableCreation** element is limited to one of the strings listed in the following table.

[Expand table](#)

Value	Description
<i>Create</i>	Create a new writeback table, if one does not exist. If a writeback table already exists, an error occurs.
<i>CreateAlways</i>	Create a new writeback table, overwriting any existing writeback table.
<i>UseExisting</i>	Use the existing writeback table, if one already exists. If one does not exist, an error occurs.

# XML Elements - Methods

Article • 12/09/2022

The XML for Analysis (XMLA) protocol uses two methods, **Discover** and **Execute**, to offer a standard way for applications to access information on an instance of Analysis Services. Because these methods are invoked by using Simple Object Access Protocol (SOAP), they accept input and deliver output in XML. Analysis Services implements both methods, in compliance with the XML for Analysis 1.1 specification.

## In this section

The following topics describe the XMLA methods implemented by Analysis Services.

  Expand table

Method	Description
<a href="#">Discover Method (XMLA)</a>	Retrieves information, such as the list of available databases or details about a specific object, from an instance of Analysis Services. The data retrieved with the <b>Discover</b> method depends on the values of the parameters passed to it.
<a href="#">Execute Method (XMLA)</a>	Sends XMLA commands to an instance of Analysis Services. This includes requests involving data transfer, such as retrieving or updating data on the server.

## Feedback

# XML Elements - Methods - Discover

Article • 12/09/2022

Retrieves information, such as the list of available databases or details about a specific object, from an instance of Analysis Services. The data retrieved with the **Discover** method depends on the values of the parameters passed to it.

**Namespace** urn:schemas-microsoft-com:xml-analysis

**SOAP Action** "urn:schemas-microsoft-com:xml-analysis:Discover"

## Syntax

XML

```
<Discover>
 <RequestType>...</RequestType>
 <Restrictions>...</Restrictions>
 <Properties>...</Properties>
</Discover>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent element	None

Relationship	Element
Child elements	<a href="#">Properties</a> , <a href="#">RequestType</a> , <a href="#">Restrictions</a>

## Remarks

The **Discover** method requests metadata about instances and objects. Metadata is returned using the XMLA [Rowset](#) data type.

### Tip

If you are unfamiliar with XML commands, click the XMLA query template on the **Query** toolbar in Management Studio, to build the query and add parameters.

## Example

In the following code sample, the client sends the **Discover** call to request a list of cubes from the Adventure Works DW Multidimensional 2012 sample Analysis Services database:

XML

```
<Discover xmlns="urn:schemas-microsoft-com:xml-analysis">
 <RequestType>MDSHEMA_CUBES</RequestType>
 <Restrictions>
 <RestrictionList>
 <CATALOG_NAME>Adventure Works DW Multidimensional
2012</CATALOG_NAME>
 </RestrictionList>
 </Restrictions>
 <Properties>
 <PropertyList>
 <DataSourceInfo>Provider=MSOLAP;Data Source=local;</DataSourceInfo>
 <Catalog>Adventure Works DW Multidimensional 2012</Catalog>
 <Format>Tabular</Format>
 </PropertyList>
 </Properties>
</Discover>
```

# XML Elements - Methods - Execute

Article • 12/09/2022

Sends XML for Analysis (XMLA) commands to an instance of Analysis Services. This includes requests involving data transfer, such as retrieving or updating data on the server.

**Namespace** urn:schemas-microsoft-com:xml-analysis

**SOAP Action** "urn:schemas-microsoft-com:xml-analysis:Execute"

## Syntax

XML
<pre>&lt;Execute&gt;   &lt;Command&gt;...&lt;/Command&gt;   &lt;Properties&gt;...&lt;/Properties&gt;   &lt;Parameters&gt;...&lt;/Parameters&gt; &lt;/Execute&gt;</pre>

## Element characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that occurs once and only once.

## Element relationships

[\[+\] Expand table](#)

Relationship	Element
Parent element	None

Relationship	Element
Child elements	<a href="#">Command</a> , <a href="#">Parameters</a> , <a href="#">Properties</a>

## Remarks

The **Execute** method executes XMLA commands provided in the **Command** element and returns any resulting data using either the XMLA [Rowset](#) data type (for tabular result sets) or the XMLA [MDDataSet](#) data type (for multidimensional result sets.)

## Example

The following code sample is an example of an **Execute** method call that contains an Multidimensional Expressions (MDX) SELECT statement.

```
XML

<Execute xmlns="urn:schemas-microsoft-com:xml-analysis">
 <Command>
 <Statement>
 SELECT [Measures].MEMBERS ON COLUMNS FROM [Adventure Works]
 </Statement>
 </Command>
 <Properties>
 <PropertyList>
 <DataSourceInfo>Provider=MSOLAP;Data Source=local;</DataSourceInfo>
 <Catalog>Adventure Works DW Multidimensional 2012</Catalog>
 <Format>Multidimensional</Format>
 <AxisFormat>ClusterFormat</AxisFormat>
 </PropertyList>
 </Properties>
</Execute>
```

# XML Elements - Objects - DiscoverResponse

Article • 12/09/2022

Contains the information returned by an instance of Analysis Services in response to a [Discover](#) method call.

Namespace `urn:schemas-microsoft-com:xml-analysis`

## Syntax

XML

```
<DiscoverResponse>
 <return>
</DiscoverResponse>
```

## Element characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">return</a>

## Remarks

The **DiscoverResponse** element is the topmost element within the body of a SOAP response for the **Discover** method.

# Analysis Services Scripting Language (ASSL for XMLA)

Article • 12/09/2022

Applies to:  SQL Server 2016 and later Analysis Services  Azure Analysis Services  
 Fabric/Power BI Premium

Applications communicate with Analysis Services using XML commands and object descriptions. Analysis Services Scripting Language (ASSL) represents the object definition language portion of this XML dialect.

This reference section contains syntax and usage information for each element in the ASSL schema.

Administrators and developers can refer to this reference section for help in understanding the scripts generated by SQL Server Management Studio, SQL Server Data Tools, Analysis Management Objects (AMO), and other applications, or for help in creating or modifying scripts for their own purposes.

## In This Section

 Expand table

Topic	Description
<a href="#">Analysis Services Scripting Language XML Element Hierarchy (ASSL)</a>	A detailed diagram of the hierarchy of elements in ASSL.

# Analysis Services Scripting Language XML Elements (ASSL)

Article • 10/31/2023

Although the Analysis Services Scripting Language (ASSL) schema contains only XML elements, from a developer's point of view, these elements correspond to the following concepts:

- Objects, such as **Database**, **Cube**, and **Dimension** objects, in the hierarchy of objects contained by an instance of Analysis Services.
- Collections of objects, such as the **Dimensions** and **Cubes** collections.
- Properties, such as **Name** and **Description**, that describe objects.
- Data types, such as **Binding** and **Permission**, that are used to define the child elements and properties of other objects.

## ⓘ Note

This section does not cover data type elements. For more information, see, [Analysis Services Scripting Language XML Data Types \(ASSL\)](#).

## In This Section

[+] Expand table

Topic	Description
<a href="#">Objects (ASSL)</a>	Contains syntax and usage information for each element that acts as an object in the ASSL schema.
<a href="#">Collections (ASSL)</a>	Contains syntax and usage information for each element that acts as a collection in the ASSL schema.
<a href="#">Properties (ASSL)</a>	Contains syntax and usage information for each element that acts as an object property in the ASSL schema.

# Collections (ASSL)

Article • 10/31/2023

This reference section contains syntax and usage information for each element that acts as a collection in the Analysis Services Scripting Language (ASSL) schema.

Although the ASSL schema contains only XML elements, from a developer's point of view, the elements described in this section correspond to collections of objects, such as the **Dimensions** and **Cubes** collections.

Collections are mostly collections of object elements, in which a plural noun designates the collection (for example, **Cubes**), and the collection contains elements designated by the same noun in the singular (for example, **Cube**).

In some cases, the schema does not adhere to this general rule. For example, the **ClassifiedColumns** collection contains **ClassifiedColumnID** elements.

In other cases, a collection contains elements that correspond to object properties, not to objects. For example, the **Aliases** collection contains **Alias** properties, each of which is a simple string value.

  Expand table

Element	Description
<a href="#">Accounts Element (ASSL)</a>	Contains the collection of account types that are defined in a <a href="#">Database</a> element.
<a href="#">Actions Element (ASSL)</a>	Contains the collection of actions for a <a href="#">Cube</a> or <a href="#">Perspective</a> element.
<a href="#">AggregationDesigns Element (ASSL)</a>	Contains the collection of aggregation designs that can be shared across multiple partitions in a database.
<a href="#">AggregationInstances Element (ASSL)</a>	Contains the collection of aggregation instances that are defined in a <a href="#">Partition</a> element.
<a href="#">Aggregations Element (ASSL)</a>	Contains the collection of aggregations defined for an <a href="#">AggregationDesign</a> element.
<a href="#">AlgorithmParameters Element (ASSL)</a>	Contains the collection of parameters for the algorithm used by a <a href="#">MiningModel</a> element.
<a href="#">Aliases Element (ASSL)</a>	Contains the collection of <a href="#">Alias</a> elements associated with an <a href="#">Account</a> element

Element	Description
<a href="#">AllMemberTranslations Element (ASSL)</a>	Contains the collection of <a href="#">Translation</a> elements for the caption of the All member of a <a href="#">Hierarchy</a> element.
<a href="#">Annotations Element (ASSL)</a>	Contains the collection of <a href="#">Annotation</a> elements associated with the parent element.
<a href="#">Assemblies Element (ASSL)</a>	Contains the collection of <a href="#">Assembly</a> elements associated with a <a href="#">Server</a> element or a <a href="#">Database</a> element.
<a href="#">AttributeAllMemberTranslations Element (ASSL)</a>	Contains the collection of translations for the caption of the All member of the dimension.
<a href="#">AttributePermissions Element (ASSL)</a>	Contains the collection of attribute permissions for an individual <a href="#">Role</a> element on a specific dimension of a <a href="#">Cube</a> element.
<a href="#">AttributeRelationships Element (ASSL)</a>	Contains the collection of <a href="#">AttributeRelationship</a> elements for the attribute.
<a href="#">Attributes Element (ASSL)</a>	Contains the collection of attributes for the associated dimension.
<a href="#">Blocks Element (ASSL)</a>	Contains the collection of blocks of binary data that represent the binary contents of a <a href="#">ClrAssemblyFile</a> element.
<a href="#">CalculationProperties Element (ASSL)</a>	Contains the collection of <a href="#">CalculationProperty</a> elements associated with an <a href="#">MdxScript</a> element.
<a href="#">Calculations Element (ASSL)</a>	Contains the collection of <a href="#">PerspectiveCalculation</a> elements associated with a <a href="#">Perspective</a> element.
<a href="#">CellPermissions Element (ASSL)</a>	Contains the collection of permissions for cells in the associated <a href="#">Cube</a> element.
<a href="#">ClassifiedColumns Element (ASSL)</a>	Contains the collection of related columns that are classified by the <a href="#">ScalarMiningStructureColumn</a> element.
<a href="#">Columns Element (ASSL)</a>	Contains the collection of columns associated with the parent element.
<a href="#">Commands Element (ASSL)</a>	Contains the collection of <a href="#">Command</a> elements associated with an <a href="#">MdxScript</a> element.
<a href="#">CubePermissions Element (ASSL)</a>	Contains the collection of permissions applicable to a <a href="#">Cube</a> element.
<a href="#">Cubes Element (ASSL)</a>	Contains the collection of <a href="#">Cube</a> elements associated with a <a href="#">Database</a> element.

Element	Description
<a href="#">DatabasePermissions Element (ASSL)</a>	Contains the collection of <a href="#">DatabasePermission</a> elements associated with a <a href="#">Database</a> element.
<a href="#">Databases Element (ASSL)</a>	Contains the collection of <a href="#">Database</a> elements associated with a <a href="#">Server</a> element.
<a href="#">DataSources Element (ASSL)</a>	Contains the collection of <a href="#">DataSourcePermission</a> elements associated with a <a href="#">DataSource</a> data type.
<a href="#">DataSourcePermissions Element (ASSL)</a>	Contains the collection of <a href="#">DataSource</a> elements associated with a <a href="#">Database</a> element.
<a href="#">DataSourceViews Element (ASSL)</a>	Contains the collection of <a href="#">DataSourceView</a> elements associated with a <a href="#">Database</a> element.
<a href="#">DimensionPermissions Element (ASSL)</a>	Contains the collection of permissions applicable to a <a href="#">Dimension</a> element or a <a href="#">CubePermission</a> element.
<a href="#">Dimensions Element (ASSL)</a>	Contains the collection of dimensions associated with the parent element.
<a href="#">Events Element (ASSL)</a>	Defines the collection of Event elements to be captured by a <a href="#">Trace</a> .
<a href="#">Files Element (ASSL)</a>	Contains the collection of <a href="#">File</a> elements that make up a <a href="#">ClrAssembly</a> element.
<a href="#">ForeignKeyColumns Element (ASSL)</a>	Contains the collection of columns that identify the join to the parent table for a relational data source.
<a href="#">Groups Element (ASSL)</a>	Contains the collection of groups of members bound to an attribute.
<a href="#">Hierarchies Element (ASSL)</a>	Contains the collection of <a href="#">Hierarchy</a> elements associated with the parent element.
<a href="#">IncrementalProcessingNotifications Element (ASSL)</a>	Contains the collection of <a href="#">IncrementalProcessingNotification</a> elements that provide information to the <a href="#">ProactiveCaching</a> element about queries to execute to determine the progress of incremental processing.
<a href="#">KeyColumns Element (ASSL)</a>	Contains the collection of <a href="#">KeyColumn</a> element definitions for a parent object.
<a href="#">Kpis Element (ASSL)</a>	Contains the collection of <a href="#">Kpi</a> elements associated with the parent element.
<a href="#">Levels Element (ASSL)</a>	Contains the collection of <a href="#">Level</a> elements in a <a href="#">Hierarchy</a> element.

Element	Description
<a href="#">MdxScripts Element (ASSL)</a>	Contains the collection of <a href="#">MdxScript</a> elements associated with a <a href="#">Cube</a> element.
<a href="#">MeasureGroups Element (ASSL)</a>	Contains the collection of <a href="#">MeasureGroup</a> elements associated with the parent element.
<a href="#">Measures Element (ASSL)</a>	Contains the collection of <a href="#">Measure</a> elements associated with the parent element.
<a href="#">Members Element (ASSL)</a>	Contains the collection of <a href="#">Member</a> elements of the parent element.
<a href="#">MiningModelPermissions Element (ASSL)</a>	Contains the collection of permissions for a <a href="#">MiningModel</a> element.
<a href="#">MiningModels Element (ASSL)</a>	Contains the collection of <a href="#">MiningModel</a> elements associated with a <a href="#">MiningStructure</a> .
<a href="#">MiningStructurePermissions Element (ASSL)</a>	Contains the collection of permissions on a <a href="#">MiningStructure</a> element.
<a href="#">MiningStructures Element (ASSL)</a>	Contains the collection of <a href="#">MiningStructure</a> elements in a <a href="#">Database</a> element.
<a href="#">ModelingFlags Element (ASSL)</a>	Contains the collection of <a href="#">ModelingFlag</a> elements for a column in a <a href="#">MiningStructure</a> or a <a href="#">MiningModel</a> .
<a href="#">NamingTemplateTranslations Element (ASSL)</a>	Provides a collection of localized translations for the <a href="#">NamingTemplate</a> element of the parent <a href="#">DimensionAttribute</a> .
<a href="#">Partitions Element (ASSL)</a>	Contains the collection of <a href="#">Partition</a> elements used by a <a href="#">MeasureGroup</a> element, or the collection of partition bindings that make up an out-of-line <a href="#">MeasureGroupBinding</a> element.
<a href="#">Perspectives Element (ASSL)</a>	Contains the collection of <a href="#">Perspective</a> elements associated with a <a href="#">Cube</a> element.
<a href="#">QueryNotifications Element (ASSL)</a>	Contains the collection of <a href="#">QueryNotification</a> elements that provide information to the <a href="#">ProactiveCaching</a> element about queries to execute to determine whether a data source has been modified.
<a href="#">ReportFormatParameters Element (ASSL)</a>	Contains the collection of <a href="#">ReportFormatParameter</a> elements for a <a href="#">ReportAction</a> element.
<a href="#">ReportParameters Element (ASSL)</a>	Contains the collection of <a href="#">ReportParameter</a> elements for a <a href="#">ReportAction</a> element.

Element	Description
Roles Element (ASSL)	Contains the collection of <a href="#">Role</a> elements defined under the parent element.
ServerProperties Element (ASSL)	Contains the collection of <a href="#">ServerProperty</a> elements associated with a <a href="#">Server</a> element.
TableNotifications Element (ASSL)	Contains the collection of <a href="#">TableNotification</a> elements that provide information for the <a href="#">ProactiveCaching</a> element about tables or views in a data source that have been modified.
Traces Element (ASSL)	Contains the collection of <a href="#">Trace</a> elements associated with a <a href="#">Server</a> element.
Translations Element (ASSL)	Contains the collection of <a href="#">Translation</a> elements associated with the parent element.
UnknownMemberTranslations Element (ASSL)	Contains the collection of translations for the caption of the <a href="#">UnknownMember</a> element of a dimension.

# Accounts Element (ASSL)

Article • 10/31/2023

Contains the collection of account types that are defined in a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <Accounts>
 <Account>...</Account>
 </Accounts>
 ...
</Database>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None (collection)
Default value	None (collection)
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	<a href="#">Account</a>

## Remarks

Dimensions, whose [Type](#) element is set to *Accounts*, can have an attribute that specifies the account type, such as Income, Expense, and so on, represented by members in the dimension. The account type is then used by [Measure](#) elements, whose [AggregationFunction](#) element is set to *ByAccount*, to determine the aggregation function to use when aggregating the members of that dimension. The [Accounts](#) element holds a collection of [Account](#) elements, which represent account types and the aggregation function that should be used for each account type.

An account type must be listed if the aggregate function is different from the default used by Analysis Services for each account type.

The set of valid account types is fixed.

The corresponding element in the Analysis Management Objects (AMO) object model is [AccountCollection](#).

---

# Actions Element (ASSL)

Article • 10/31/2023

Contains the collection of actions for a [Cube](#) or [Perspective](#) element.

## Syntax

XML

```
<Cube> <!-- or Perspective -->
...
<Actions>
 <Action xsi:type="DrillThroughAction">...</Action> <!-- ancestor: Cube
-->
 <Action xsi:type="ReportAction">...</Action> <!-- ancestor: Cube -->
 <Action xsi:type="StandardAction">...</Action> <!-- ancestor: Cube -->
 <!-- or -->
 <Action xsi:type="PerspectiveAction">...</Action> <!-- ancestor:
Perspective -->
</Actions>
...
</Cube>
```

## Element Characteristics

# AlgorithmParameters Element (ASSL)

Article • 10/31/2023

Contains the collection of parameters for the algorithm used by a [MiningModel](#) element.

## Syntax

XML

```
<MiningModel>
 ...
 <AlgorithmParameters>
 <AlgorithmParameter>...</AlgorithmParameter>
 </AlgorithmParameters>
 ...
</MiningModel>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None (collection)
Default value	None (collection)
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">MiningModel</a>
Child elements	<a href="#">AlgorithmParameter</a>

## Remarks

The **AlgorithmParameters** collection contains an extensible set of parameters, represented as name/value pairs, for a mining model algorithm. The set of applicable parameters is algorithm-dependent. For more information about algorithm parameters for a given algorithm, see the appropriate documentation for that algorithm.

Available algorithm parameters, including validation and display information, can be retrieved from the **DMSHEMA\_MINING\_SERVICE\_PARAMETERS** schema rowset.

The corresponding element in the Analysis Management Objects (AMO) object model is [AlgorithmParameterCollection](#).

# Blocks Element (ASSL)

Article • 10/31/2023

Contains the collection of blocks of binary data that represent the binary contents of a [ClrAssemblyFile](#) element.

## Syntax

XML

```
<Data xsi:type="DataBlock">
 ...
 <Blocks>
 <Block>...</Block>
 </Blocks>
 ...
</File>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	Data of type <a href="#">DataBlock</a>
Child elements	<a href="#">Block</a>

## Remarks

The element that corresponds to the parent of **Blocks** in the Analysis Management Objects (AMO) object model is [ClrAssemblyFile](#).

---

 Yes

 No

# CalculationProperties Element (ASSL)

Article • 10/31/2023

Contains the collection of [CalculationProperty](#) elements associated with an [MdxScript](#) element.

## Syntax

XML

```
<MdxScript>
 ...
 <CalculationProperties>
 <CalculationProperty>...</CalculationProperty>
 </CalculationProperties>
 ...
</MdxScript>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">MdxScript</a>
Child elements	<a href="#">CalculationProperty</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [CalculationPropertyCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# Calculations Element (ASSL)

Article • 10/31/2023

Contains the collection of [PerspectiveCalculation](#) elements associated with a [Perspective](#) element.

## Syntax

XML

```
<Perspective>
 ...
 <Calculations>
 <Calculation xsi:type="PerspectiveCalculation">...</Calculation>
 </Calculations>
 ...
</Perspective>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Perspective</a>
Child elements	<a href="#">Calculation</a> of type <a href="#">PerspectiveCalculation</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveCalculationCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# CellPermissions Element (ASSL)

Article • 10/31/2023

Contains the collection of permissions for cells in the associated [Cube](#) element.

## Syntax

XML

```
<CubePermission>
 ...
 <CellPermissions>
 <CellPermission>...</CellPermission>
 </CellPermissions>
 ...
</CubePermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CubePermission</a>
Child elements	<a href="#">CellPermission</a>

## Remarks

The collection can contain up to one **CellPermission** object for each allowed value of the [Access](#) element.

The corresponding element in the Analysis Management Objects (AMO) object model is [CellPermissionCollection](#).

---

## Feedback

Was this page helpful?

Yes

No

# ClassifiedColumns Element (ASSL)

Article • 10/31/2023

Contains the collection of related columns that are classified by the [ScalarMiningStructureColumn](#) element.

## Syntax

XML

```
<MiningStructureColumn xsi:type="ScalarMiningStructureColumn">
 ...
 <ClassifiedColumns>
 <ClassifiedColumnID>...</ClassifiedColumnID>
 </ClassifiedColumns>
 ...
</MiningStructureColumn>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">MiningStructureColumn</a> of type <a href="#">ScalarMiningStructureColumn</a>
Child elements	<a href="#">ClassifiedColumnID</a>

## Remarks

The element that corresponds to the parent of **ClassifiedColumns** in the Analysis Management Objects (AMO) object model is [ScalarMiningStructureColumn](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# Columns Element (ASSL)

Article • 10/31/2023

Contains the collection of columns associated with the parent element.

## Syntax

XML

```
<Action xsi:type="DrillThroughAction"> <!-- or one of the elements listed
below in the Element Relationships table -->
 <Columns>
 <Column xsi:type="MeasureBinding">...</Column> <!-- parent:
DrillThroughAction -->
 <!-- or -->
 <Column xsi:type="CubeAttributeBinding">...</Column> <!-- parent:
DrillThroughAction -->
 <!-- or -->
 <Column xsi:type="EventColumn">...</Column> <!-- parent: Event -->
 <!-- or -->
 <Column xsi:type="MiningModelColumn">...</Column> <!-- parent:
MiningModel or MiningModelColumn -->
 <!-- or -->
 <Column xsi:type="MiningStructureColumn">...</Column> <!-- parent:
MiningStructure or TableMiningStructureColumn -->
 </Columns>
</DrillThroughAction>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	See the table below.

[ ] Expand table

Ancestor or Parent	Cardinality
Event	1-1: Required element that occurs once and only once.
All others	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	Action of type <a href="#">DrillThroughAction</a> , <a href="#">Event</a> , <a href="#">MiningModel</a> , <a href="#">MiningModelColumn</a> , <a href="#">MiningStructure</a> , <a href="#">TableMiningStructureColumn</a>
Child elements	See the table below.

[+] [Expand table](#)

Ancestor or Parent	Child Elements
<a href="#">DrillThroughAction</a>	<a href="#">CubeAttributeBinding</a> or <a href="#">MeasureBinding</a>
<a href="#">Event</a>	<a href="#">EventColumn</a>
<a href="#">MiningModel</a> , <a href="#">MiningModelColumn</a>	<a href="#">MiningModelColumn</a>
<a href="#">MiningStructure</a> , <a href="#">TableMiningStructureColumn</a>	<a href="#">MiningStructureColumn</a>

## Remarks

For **DrillThroughAction** elements, the **Columns** collection identifies the columns that contain data to be returned when the action is performed.

For **TableMiningStructureColumn** elements, the **Columns** collection allows only one level of recursion. In other words, any **TableMiningStructureColumn** element included in this collection cannot contain any **TableMiningStructureColumn** elements in its **Columns** collection.

Some of the corresponding elements in the Analysis Management Objects (AMO) object model are [TraceColumnCollection](#), [MiningModelColumnCollection](#), and [MiningStructureColumnCollection](#).

 Yes

 No

# Commands Element (ASSL)

Article • 10/31/2023

Contains the collection of [Command](#) elements associated with an [MdxScript](#) element.

## Syntax

XML

```
<MdxScript>
 ...
 <Commands>
 <Command>...</Command>
 ...</Commands>
 ...
</MdxScript>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MdxScript</a>
Child elements	<a href="#">Command</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [CommandCollection](#).

 No

# Cubes Element (ASSL)

Article • 10/31/2023

Contains the collection of [Cube](#) elements associated with a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <Cubes>
 <Cube>...</Cube>
 </Cubes>
 ...
</Database>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element

# Databases Element (ASSL)

Article • 10/31/2023

Contains the collection of [Database](#) elements associated with a [Server](#) element.

## Syntax

XML

```
<Server>
 ...
 <Databases>
 <Database>...</Database>
 </Databases>
 ...
</Server>
```

## Element Characteristics

  [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

  [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Server</a>
Child elements	<a href="#">Database</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [DatabaseCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# DataSourcePermissions Element (ASSL)

Article • 10/31/2023

Contains the collection of [DataSourcePermission](#) elements associated with a [DataSource](#) data type.

## Syntax

XML

```
<DataSource>
 ...
 <DataSourcePermissions>
 <DataSourcePermission>...</DataSourcePermission>
 </DataSourcePermissions>
 ...
</DataSource>
```

## Element Characteristics

  [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

  [Expand table](#)

Relationship	Element
Parent elements	<a href="#">DataSource</a>
Child elements	<a href="#">DataSourcePermission</a>

# Remarks

 Yes

 No

# DataSources Element (ASSL)

Article • 10/31/2023

Contains the collection of [DataSource](#) elements associated with a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <DataSources>
 <DataSource>...</DataSource>
 </DataSources>
 ...
</Database>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	<a href="#">DataSource</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [DataSourceCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# DataSourceViews Element (ASSL)

Article • 10/31/2023

Contains the collection of [DataSourceView](#) elements associated with a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <DataSourceViews>
 <DataSourceView>...</DataSourceView>
 </DataSourceViews>
 ...
</Database>
```

## Element Characteristics

  Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

  Expand table

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	<a href="#">DataSourceView</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [DataSourceViewCollection](#).

# DimensionPermissions Element (ASSL)

Article • 10/31/2023

Contains the collection of permissions applicable to a [Dimension](#) element or a [CubePermission](#) element.

## Syntax

XML

```
<Dimension> <!-- or CubePermission -->
...
<DimensionPermissions>
 <DimensionPermission>...</DimensionPermission> <!-- parent:
Dimension -->
 <!-- or -->
 <DimensionPermission xsi:type="CubeDimensionPermission">...
</DimensionPermission> <!-- parent: CubePermission -->
 </DimensionPermissions>
...
</Dimension>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CubePermission</a> , <a href="#">Dimension</a>

Relationship	Element
Child elements	<a href="#">DimensionPermission</a>

## Remarks

For **CubePermission** elements, **DimensionPermission** elements in this collection override permissions specified in the **DimensionPermissions** collection of each dimension explicitly referenced. If a dimension is not referenced in this collection, then the **CubePermission** element inherits the permissions specified in the **DimensionPermissions** collection of the dimension.

The corresponding element in the Analysis Management Objects (AMO) object model is [DimensionPermissionCollection](#).

---

# ForeignKeyColumns Element (ASSL)

Article • 10/31/2023

Contains the collection of columns that identify the join to the parent table for a relational data source.

## Syntax

XML

```
<MiningStructureColumn xsi:type="TableMiningStructureColumn">
 ...
 <ForeignKeyColumns>
 <ForeignKeyColumn xsi:type="DataItem">...</ForeignKeyColumn>
 ...</ForeignKeyColumns>
 ...
</MiningStructureColumn>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

# KeyColumns Element (ASSL)

Article • 10/31/2023

Contains the collection of [KeyColumn](#) element definitions for a parent object.

## Syntax

XML

```
<DimensionAttribute> <!-- or AggregationInstanceAttribute,
AggregationInstanceCubeDimension, MeasureGroupAttribute,
ScalarMiningStructureColumn -->
...
<KeyColumns>
 <KeyColumn xsi:type="DataItem" ...></KeyColumn>
</KeyColumns>
...
</Dimension>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-n: Required element that can occur more than once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">AggregationInstanceAttribute</a> , <a href="#">AggregationInstanceCubeDimension</a> , <a href="#">DimensionAttribute</a> , <a href="#">MeasureGroupAttribute</a> , <a href="#">ScalarMiningStructureColumn</a>
Child elements	<a href="#">KeyColumn</a> of type <a href="#">DataItem</a>

## Remarks

The **KeyColumns** collection can contain multiple **KeyColumn** elements that represent a multipart key for an attribute or mining structure column.

---

 No

# MiningModelPermissions Element (ASSL)

Article • 10/31/2023

Contains the collection of permissions for a [MiningModel](#) element.

## Syntax

```
XML

<MiningModel>
 ...
 <MiningModelPermissions>
 <MiningModelPermission xsi:type="Permission">...
 </MiningModelPermission>
 </MiningModelPermissions>
 ...
</MiningModel>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">MiningModel</a>
Child elements	<a href="#">MiningModelPermission</a> of type <a href="#">Permission</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [MiningModelPermissionCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# MiningModels Element (ASSL)

Article • 10/31/2023

Contains the collection of [MiningModel](#) elements associated with a [MiningStructure](#).

## Syntax

XML

```
<MiningStructure>
 ...
 <MiningModels>
 <MiningModel>...</MiningModel>
 </MiningModels>
 ...
</MiningStructure>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

## Feedback

Was this page helpful?

 Yes

 No

# MiningStructurePermissions Element (ASSL)

Article • 10/31/2023

Contains the collection of permissions on a [MiningStructure](#) element.

## Syntax

```
XML

<MiningStructure>
 ...
 <MiningStructurePermissions>
 <MiningStructurePermission xsi:type="Permission">...
 </MiningStructurePermission>
 </MiningStructurePermissions>
 ...
</MiningStructure>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningStructure</a>
Child elements	<a href="#">MiningStructurePermission</a> of type <a href="#">Permission</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [MiningStructurePermissionCollection](#).

---

# MiningStructures Element (ASSL)

Article • 10/31/2023

Contains the collection of [MiningStructure](#) elements in a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <MiningStructures>
 <MiningStructure>...</MiningStructure>
 </MiningStructures>
 ...
</Database>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

# ModelingFlags Element (ASSL)

Article • 10/31/2023

Contains the collection of [ModelingFlag](#) elements for a column in a [MiningStructure](#) or a [MiningModel](#).

## Syntax

XML

```
<MiningModelColumn> <!-- or ScalarMiningStructureColumn -->
 ...
 <ModelingFlags>
 <ModelingFlag xsi:type="MiningModelingFlag">...</ModelingFlag>
 </ModelingFlags>
 ...
</MiningModelColumn>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

 Yes

 No

# NamingTemplateTranslations Element (ASSL)

Article • 10/31/2023

Provides a collection of localized translations for the [NamingTemplate](#) element of the parent, [DimensionAttribute](#).

## Syntax

XML

```
<Attribute xsi:type="DimensionAttribute">
 ...
 <NamingTemplateTranslations>
 <NamingTemplateTranslation xsi:type="Translation">...
 </NamingTemplateTranslation>
 ...
</Attribute>
```

## Element Characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Attribute</a> of type <a href="#">DimensionAttribute</a>

Relationship	Element
Child elements	<a href="#">NamingTemplateTranslation</a> of type <a href="#">Translation</a>

## Remarks

The value of the **NamingTemplateTranslation** element is used only by parent attributes (in other words, the value of the [Usage](#) element of the parent **DimensionAttribute** is set to *Parent*.)

The corresponding element in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# Partitions Element (ASSL)

Article • 10/31/2023

Contains the collection of [Partition](#) elements used by a [MeasureGroup](#) element, or the collection of partition bindings that make up an out-of-line [MeasureGroupBinding](#) element.

## Syntax

```
XML

<MeasureGroup> <!-- or MeasureGroupBinding -->
 ...
 <Partitions>
 <Partition>...</Partition> <!-- parent: MeasureGroup -->
 <!-- or -->
 <Partition xsi:type="PartitionBinding">...</Partition> <!-- parent:
 MeasureGroupBinding -->
 </Partitions>
 ...
</MeasureGroup>
```

## Element Characteristics

# Perspectives Element (ASSL)

Article • 10/31/2023

Contains the collection of [Perspective](#) elements associated with a [Cube](#) element.

## Syntax

XML

```
<Cube>
 ...
 <Perspectives>
 <Perspective>...</Perspective>
 </Perspectives>
 ...
</Cube>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Cube</a>
Child elements	<a href="#">Perspective</a>

 No

# QueryNotifications Element (ASSL)

Article • 10/31/2023

Contains the collection of [QueryNotification](#) elements that provide information to the [ProactiveCaching](#) element about queries to execute to determine whether a data source has been modified.

## Syntax

XML

```
<ProactiveCachingQueryBinding>
 ...
 <QueryNotifications>
 <QueryNotification>...</QueryNotification>
 ...</QueryNotifications>
 ...
</ProactiveCachingQueryBinding>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">ProactiveCachingQueryBinding</a>
Child elements	<a href="#">QueryNotification</a>

# Relationships Element (ASSL)

Article • 10/31/2023

Contains the collection of relationships for the associated dimension.

## Syntax

XML

```
<CubeDimension> <!-- or one of the elements listed below in the Element
Relationships table -->
 ...
 <Attributes>
 <Attribute>...</Attribute>
 </Attributes>
 ...
</CubeDimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

Relationship	Element
Parent elements	<a href="#">CubeDimension</a> , <a href="#">Dimension</a> , <a href="#">PerspectiveDimension</a> , <a href="#">RegularMeasureGroupDimension</a>
Child elements	<a href="#">Relationship</a>

## Remarks

The corresponding elements in the Analysis Management Objects (AMO) object model are [RelationshipCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# ReportFormatParameters Element (ASSL)

Article • 10/31/2023

Contains the collection of [ReportFormatParameter](#) elements for a [ReportAction](#) element.

## Syntax

XML
<pre>&lt;Action xsi:type="ReportAction"&gt;   ...   &lt;ReportFormatParameters&gt;     &lt;ReportFormatParameter&gt;...&lt;/ReportFormatParameter&gt;   &lt;/ReportFormatParameters&gt;   ... &lt;/Action&gt;</pre>

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Action</a> of type <a href="#">ReportAction</a>
Child elements	<a href="#">ReportFormatParameter</a>

## Remarks

The element that corresponds to the parent of **ReportFormatParameters** in the Analysis Management Objects (AMO) object model is [ReportAction](#).

---

## Feedback

Was this page helpful?

# ReportParameters Element (ASSL)

Article • 10/31/2023

Contains the collection of [ReportParameter](#) elements for a [ReportAction](#) element.

## Syntax

XML

```
<Action xsi:type="ReportAction">
 ...
 <ReportParameters>
 <ReportParameter>...</ReportParameter>
 </ReportParameters>
 ...
</Action>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Action</a> of type <a href="#">ReportAction</a>
Child elements	<a href="#">ReportParameter</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [ReportParameterCollection](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# Roles Element (ASSL)

Article • 10/31/2023

Contains the collection of [Role](#) elements defined under the parent element.

## Syntax

XML

```
<Database> <!-- or Server -->
...
<Roles>
 <Role>...</Role>
</Roles>
...
</Database>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">Database</a> , <a href="#">Server</a>
Child elements	<a href="#">Role</a>

## Remarks

The **Roles** element associated with a **Server** element contains only one role, named Administrators, which represents the server administrator role. The server administrator role cannot be changed or deleted, nor can additional roles be added to the collection.

The **Roles** element associate with a **Database** element contains the roles defined for that database.

The corresponding element in the Analysis Management Objects (AMO) object model is [RoleCollection](#).

# ServerProperties Element (ASSL)

Article • 10/31/2023

Contains the collection of [ServerProperty](#) elements associated with a [Server](#) element.

## Syntax

XML

```
<Server>
 ...
 <ServerProperties>
 <ServerProperty>...</ServerProperty>
 </ServerProperties>
 ...
</Server>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Server</a>
Child elements	<a href="#">ServerProperty</a>

 No

# TableNotifications Element (ASSL)

Article • 10/31/2023

Contains the collection of [TableNotification](#) elements that provide information for the [ProactiveCaching](#) element about tables or views in a data source that have been modified.

## Syntax

XML

```
<ProactiveCachingTablesBinding>
 <TableNotifications>
 <TableNotification>...</TableNotification>
 ...</TableNotifications>
</ProactiveCachingTablesBinding>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

## Feedback

Was this page helpful?

 Yes

 No

# Traces Element (ASSL)

Article • 10/31/2023

Contains the collection of [Trace](#) elements associated with a [Server](#) element.

## Syntax

XML

```
<Server>
 ...
 <Traces>
 <Trace>...</Trace>
 </Traces>
 ...
</Server>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

 No

# Translations Element (ASSL)

Article • 10/31/2023

Contains the collection of [Translation](#) elements associated with the parent element.

## Syntax

XML

```
<Action><!-- or one of the elements listed below in the Element
Relationships table -->
...
<Translations>
 <Translation>...</Translation>
 <!-- or -->
 <Translation xsi:type="AttributeTranslation">...</Translation><!--
parent: DimensionAttribute or ScalarMiningStructureColumn -->
 <!-- or -->
 <Translation xsi:type="RelationshipEndTranslation">...</Translation>
<!-- parent: RelationshipEnd -->
</Translations>
...
</Action>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

# Analysis Services Scripting Language XML Data Types (ASSL)

Article • 10/31/2023

This reference section contains syntax and usage information for each element that acts as a type in the Analysis Services Scripting Language (ASSL) schema.

Although the ASSL schema contains only XML elements, from a developer's point of view, the elements described in this section correspond to types, such as **Binding** and **Permission**, which are used to define the child elements and properties of other objects.

Type elements, like **objects** elements, are never leaf-level elements in the ASSL schema, but have child elements and elements that correspond to object properties.

However a type element never appears as an element in a script that defines or describes Analysis Services objects. Instead it appears as the type of other object elements, normally designated with the **type** attribute from the XML Schema Instance schema using **xsi:type** or **xs:type**. For example, `<Assembly xsi:type="ClrAssembly">...</Assembly>.`

In some cases, a type derives from another type. For example, the **CubeBinding** type derives from the parent **Binding** type.

[+] Expand table

Element	Description
<a href="#">Action Data Type (ASSL)</a>	Defines an abstract primitive data type that represents an action in a <a href="#">Cube</a> element or a <a href="#">Perspective</a> element.
<a href="#">AggregationAttribute Data Type (ASSL)</a>	Defines a primitive data type that represents the association between an <a href="#">Aggregation</a> element and an attribute.
<a href="#">AggregationDesignAttribute Data Type (ASSL)</a>	Defines a primitive data type that represents the association between an attribute and an <a href="#">AggregationDesignDimension</a> element.
<a href="#">AggregationDesignDimension Data Type (ASSL)</a>	Defines a primitive data type that represents the relationship between a cube dimension and an <a href="#">AggregationDesign</a> element.
<a href="#">AggregationDimension Data Type (ASSL)</a>	Defines a primitive data type that represents the relationship between a dimension and an

Element	Description
	Aggregation element.
AggregationInstanceAttribute Data Type (ASSL)	Defines a primitive data type that represents information about an attribute used by an aggregation instance.
AggregationInstanceCubeDimension Data Type (ASSL)	Defines a primitive data type that represents information about a cube dimension used by an aggregation instance.
AggregationInstanceMeasure Data Type (ASSL)	Defines a primitive data type that represents information about a measure used by an aggregation instance.
Assembly Data Type (ASSL)	Defines an abstract primitive data type that represents an assembly or a COM dynamic link library (DLL) associated with a <a href="#">Server</a> or <a href="#">Database</a> element.
AttributeBinding Data Type (ASSL)	Defines a derived data type that represents a binding for an <a href="#">Attribute</a> element.
AttributeTranslation Data Type (ASSL)	Defines a derived data type that represents a translation associated with an <a href="#">Attribute</a> element
Binding Data Type (ASSL)	Defines an abstract primitive data type that represents a dependent relationship between two objects in which the data or metadata of one object is dependent on the data or metadata of a bound object.
ClrAssembly Data Type (ASSL)	Defines a derived data type that represents a Microsoft .NET Framework assembly associated with a <a href="#">Database</a> or <a href="#">Server</a> element
ClrAssemblyFile Data Type (ASSL)	Defines a primitive data type that represents one of the files that compose a Microsoft .NET Framework assembly ( <a href="#">ClrAssembly</a> element).
ColumnBinding Data Type (ASSL)	Defines a derived data type that represents the binding of a column in a data source view to a <a href="#">DataItem</a> element.
ComAssembly Data Type (ASSL)	Defines a derived data type that represents a COM library associated with a <a href="#">Server</a> or <a href="#">Database</a> element.
CubeAttribute Data Type (ASSL)	Defines a primitive data type that represents an attribute associated with a <a href="#">Cube</a> element.

Element	Description
<a href="#">CubeAttributeBinding Data Type (ASSL)</a>	Defines a derived data type that represents the binding of an attribute in a cube dimension to either an action or a mining structure column.
<a href="#">CubeBinding Data Type (out-of-line) (ASSL)</a>	Defines a primitive data type that represents the relationship between a <a href="#">Cube</a> element and a <a href="#">DataSource</a> element.
<a href="#">CubeDimension Data Type (ASSL)</a>	Defines a primitive data type that represents the relationship between a dimension and a cube.
<a href="#">CubeDimensionBinding Data Type (ASSL)</a>	Defines a derived data type that represents the binding of a <a href="#">Dimension</a> , <a href="#">Measure</a> , or <a href="#">MiningModel</a> element to a cube dimension.
<a href="#">CubeDimensionPermission Data Type (ASSL)</a>	Defines a primitive data type that represents the permissions for a single role on a specific dimension in a cube.
<a href="#">CubeHierarchy Data Type (ASSL)</a>	Defines a primitive data type that represents information about a <a href="#">Hierarchy</a> element in a <a href="#">Cube</a> element.
<a href="#">DataBlock Data Type (ASSL)</a>	Defines a primitive data type that represents a collection of data blocks used to store the binary contents of a <a href="#">ClrAssemblyFile</a> element.
<a href="#">DataItem Data Type (ASSL)</a>	Defines a primitive data type that represents the data-related characteristics of a data item, such as a column or attribute.
<a href="#">DataMiningMeasureGroupDimension Data Type (ASSL)</a>	Defines a derived data type that represents the relationship between a measure group and a data mining dimension.
<a href="#">DataSource Data Type (ASSL)</a>	Defines an abstract primitive data type that represents a data source in a <a href="#">Database</a> element.
<a href="#">DataSourceViewBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding between a data source view and the parent element.
<a href="#">DegenerateMeasureGroupDimension Data Type (ASSL)</a>	Defines a derived data type that represents the relationship between a degenerate dimension (that is, a fact dimension) and a measure group.

Element	Description
Dimension Data Type (ASSL)	Defines a primitive data type that represents a database dimension.
DimensionAttribute Data Type (ASSL)	Defines a primitive data type that represents an attribute in a dimension.
DimensionBinding Data Type (ASSL)	Defines a derived data type that represents the binding between a data source and a <a href="#">Dimension</a> element.
DimensionPermission Data Type (ASSL)	Defines a derived data type that represents the permissions assigned to a database dimension.
DrillThroughAction Data Type (ASSL)	Defines a derived data type that represents a drillthrough action.
DSVTableBinding Data Type (ASSL)	Defines a derived data type that represents the binding between a table and a <a href="#">DataSourceView</a> element.
EventColumn Data Type (ASSL)	Defines a primitive data type that represents a column of information to be captured for an <a href="#">Event</a> element as part of a <a href="#">Trace</a> element.
Hierarchy Data Type (ASSL)	Defines a primitive data type that represents a hierarchy in a dimension.
ImpersonationInfo Data Type (ASSL)	Defines a primitive data type that represents the information used to impersonate a user.
IncrementalProcessingNotification Data Type (ASSL)	Defines a derived data type which represents information for the <a href="#">ProactiveCaching</a> element about a query to execute to determine the progress of incremental processing.
InheritedBinding Data Type (ASSL)	Defines a derived data type that indicates that a <a href="#">MeasureGroupAttribute</a> element inherits its bindings from the attribute.
ManyToManyMeasureGroupDimension Data Type (ASSL)	Defines a derived data type that represents the relationship between a many-to-many dimension and a measure group.
MeasureBinding Data Type (ASSL)	Defines a derived data type which represents the binding of a measure to the parent element.
MeasureGroupAttribute Data Type (ASSL)	Defines a primitive data type that represents the relationship between an attribute and a

Element	Description
	measure group.
<a href="#">MeasureGroupBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding to a <a href="#">MeasureGroup</a> element.
<a href="#">MeasureGroupBinding Data Type (out-of-line) (ASSL)</a>	Defines a primitive data type that represents a binding to a measure group.
<a href="#">MeasureGroupDimension Data Type (ASSL)</a>	Defines an abstract primitive data type that represents the relationship between a dimension and a measure group.
<a href="#">MeasureGroupDimensionBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding between a dimension and a measure group.
<a href="#">MeasureGroupHierarchy Data Type (ASSL)</a>	Defines a primitive data type that represents information about a hierarchy in a measure group.
<a href="#">MiningModelColumn Data Type (ASSL)</a>	Defines a primitive data type that represents information about a column in a <a href="#">MiningModel</a> element.
<a href="#">MiningModelingFlag Data Type (ASSL)</a>	Defines a primitive data type that represents the available modeling flags for a <a href="#">ModelingFlag</a> element.
<a href="#">MiningStructureColumn Data Type (ASSL)</a>	Defines an abstract primitive data type that represents information about a column in a <a href="#">MiningStructure</a> element.
<a href="#">OlapDataSource Data Type (ASSL)</a>	Defines a derived data type that represents a multidimensional <a href="#">DataSource</a> element.
<a href="#">PartitionBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding to a <a href="#">Partition</a> element.
<a href="#">Permission Data Type (ASSL)</a>	Defines an abstract primitive data type that represents information about an individual permission.
<a href="#">PerspectiveAction Data Type (ASSL)</a>	Defines a primitive data type that represents information about an action in a <a href="#">Perspective</a> element.
<a href="#">PerspectiveAttribute Data Type (ASSL)</a>	Defines a primitive data type that represents information about an attribute in a <a href="#">PerspectiveDimension</a> element.

Element	Description
PerspectiveCalculation Data Type (ASSL)	Defines a primitive data type that represents the relationship between a calculation and a <a href="#">Perspective</a> element.
PerspectiveDimension Data Type (ASSL)	Defines a primitive data type that represents information about a dimension in a perspective.
PerspectiveHierarchy Data Type (ASSL)	Defines a primitive data type that represents information about a hierarchy in a <a href="#">PerspectiveDimension</a> element.
PerspectiveKpi Data Type (ASSL)	Defines a primitive data type that represents information about a key performance indicator (KPI) in a <a href="#">Perspective</a> element.
PerspectiveMeasure Data Type (ASSL)	Defines a primitive data type that represents information about a measure in a <a href="#">PerspectiveMeasureGroup</a> element.
PerspectiveMeasureGroup Data Type (ASSL)	Defines a primitive data type that represents information about a measure group in a <a href="#">Perspective</a> element.
ProactiveCachingBinding Data Type (ASSL)	Defines an abstract derived data type that represents information to the <a href="#">ProactiveCaching</a> element about data source changes that require rebuilding the cache, or about the status of the rebuilding process.
ProactiveCachingIncrementalProcessingBinding Data Type (ASSL)	Defines a derived data type that represents a binding to the <a href="#">ProactiveCaching</a> element about the status of the process of rebuilding the cache.
ProactiveCachingInheritedBinding Data Type (ASSL)	Defines a derived data type that represents information to the <a href="#">ProactiveCaching</a> element about data source changes in tables and views identified through existing data bindings that require rebuilding the cache.
ProactiveCachingObjectNotificationBinding Data Type (ASSL)	Defines an abstract derived data type that represents information to the <a href="#">ProactiveCaching</a> element about data source changes, either in specified tables and views or in tables and views identified through existing data bindings that require rebuilding the cache.

Element	Description
<a href="#">ProactiveCachingQueryBinding Data Type (ASSL)</a>	Defines a derived data type that represents information to the <a href="#">ProactiveCaching</a> element about data source changes in tables and views, identified through the execution of the specified queries that require rebuilding the cache.
<a href="#">ProactiveCachingTablesBinding Data Type (ASSL)</a>	Defines a derived data type that represents information to the <a href="#">ProactiveCaching</a> element about data source changes in specified tables and views that require rebuilding the cache.
<a href="#">PushedDataSource Data Type (ASSL)</a>	Defines a primitive data type that represents a data source used for "pushing" data into a <a href="#">Cube</a> element.
<a href="#">QueryBinding Data Type (ASSL)</a>	Defines a derived data type that represents the association of a <a href="#">DataSource</a> element with a <a href="#">QueryDefinition</a> element.
<a href="#">ReferenceMeasureGroupDimension Data Type (ASSL)</a>	Defines a derived data type that represents a dimension that is indirectly related to the fact table through an intermediate dimension. (For example, a Sales measure group can reference a Geography dimension, which is related through the Customer dimension.)
<a href="#">RegularMeasureGroupDimension Data Type (ASSL)</a>	Defines a derived data type that represents a regular relationship between a dimension and a measure group.
<a href="#">RelationalDataSource Data Type (ASSL)</a>	Defines a derived data type that represents a <a href="#">DataSource</a> element based on a relational data source.
<a href="#">ReportAction Data Type (ASSL)</a>	Defines a derived data type that represents an action that generates a Reporting Services report.
<a href="#">RowBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding to the rows of a table in a <a href="#">DataSourceView</a> element.
<a href="#">ScalarMiningStructureColumn Data Type (ASSL)</a>	Defines a derived data type that represents a <a href="#">MiningStructureColumn</a> element that contains scalar values, as opposed to the nested tables associated with the <a href="#">TableMiningStructureColumn</a> element that contains nested tables.

Element	Description
<a href="#">StandardAction Data Type (ASSL)</a>	Defines a derived data type that represents any <a href="#">Action</a> element other than a <a href="#">DrillThroughAction</a> element or a <a href="#">ReportAction</a> element.
<a href="#">TableBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding to a table.
<a href="#">TableMiningStructureColumn Data Type (ASSL)</a>	Defines a derived data type that represents a <a href="#">MiningStructureColumn</a> element that contains nested tables, as opposed to the scalar values associated with the <a href="#">ScalarMiningStructureColumn</a> element that contains scalar values.
<a href="#">TabularBinding Data Type (ASSL)</a>	Defines an abstract derived data type that represents a binding to a tabular item such as a table or a cube dimension.
<a href="#">TimeAttributeBinding Data Type (ASSL)</a>	Defines a derived data type that represents a "placeholder" binding for generated data items in a server time dimension, such as the key columns of an attribute.
<a href="#">TimeBinding Data Type (ASSL)</a>	Defines a derived data type that represents a binding to time periods.
<a href="#">Translation Data Type (ASSL)</a>	Defines a primitive data type that represents a localized translation.
<a href="#">UserDefinedGroupBinding Data Type (ASSL)</a>	Defines a derived data type that represents a user-defined grouping for an attribute.

# Action Data Type (ASSL)

Article • 10/31/2023

Defines an abstract primitive data type that represents an action in a [Cube](#) element or a [Perspective](#) element.

## Syntax

XML

```
<Action>
 <Name>...</Name>
 <ID>...</ID>
 <Caption>...</Caption>
 <CaptionIsMdx>...</CaptionIsMdx>
 <Translations>...</Translations>
 <TargetType>...</TargetType>
 <Target>...</Target>
 <Condition>...</Condition>
 <Type>...</Type>
 <Invocation>...</Invocation>
 <Application>...</Application>
 <Description>...</Description>
 <Annotations>...</Annotations>
</Action>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	<a href="#">DrillThroughAction</a> , <a href="#">ReportAction</a> , <a href="#">StandardAction</a>

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Actions</a>
Child elements	<a href="#">Annotations</a> , <a href="#">Application</a> , <a href="#">Caption</a> , <a href="#">CaptionIsMdx</a> , <a href="#">Condition</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">Invocation</a> , <a href="#">Name</a> , <a href="#">Target</a> , <a href="#">TargetType</a> , <a href="#">Translations</a> , <a href="#">Type</a>
Derived elements	<a href="#">DrillThroughAction</a> , <a href="#">ReportAction</a> , <a href="#">StandardAction</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [Action](#).

---

# Assembly Data Type (ASSL)

Article • 10/31/2023

Defines an abstract primitive data type that represents a Microsoft .NET Framework assembly or a COM dynamic link library (DLL) associated with a [Server](#) or [Database](#) element.

## ⓘ Important

COM assemblies might pose a security risk. Due to this risk and other considerations, COM assemblies are deprecated.

## Syntax

XML

```
<Assembly>
 <Name>...</Name>
 <ID>...</ID>
 <Description>...</Description>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <ImpersonationInfo>...</ImpersonationInfo>
 <Annotations>...</Annotations>
</Assembly>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	ClrAssembly, ComAssembly

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">CreatedTimestamp</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">ImpersonationInfo</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">Name</a>
Derived elements	None

## Remarks

The **Assembly** data type serves as the base data type for the **ComAssembly** element, which represents COM libraries associated with the instance or database, and the **ClrAssembly** element, which represents assemblies associated with the instance or database.

The corresponding element in the Analysis Management Objects (AMO) object model is [Assembly](#).

## Feedback

# ClrAssembly Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a Microsoft .NET Framework assembly associated with a [Database](#) or [Server](#) element

## Syntax

XML

```
<ClrAssembly>
 <!-- The following elements extend Assembly -->
 <Files>...</Files>
 <PermissionSet>...</PermissionSet>
</ClrAssembly>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	<a href="#">Assembly</a>
Derived data types	None

## Data Type Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	None (abstract type)
Child elements	<a href="#">Files</a> , <a href="#">PermissionSet</a>
Derived elements	See <a href="#">Assembly</a> ( <a href="#">Assemblies</a> collection of <a href="#">Database</a> or <a href="#">Server</a> )

## Remarks

The **ClrAssembly** element contains the files needed to recreate a Microsoft .NET Framework assembly, associated either with an instance of Analysis Services or with a specific database on an instance, as well as the permissions needed to execute the assembly.

The corresponding element in the Analysis Management Objects (AMO) object model is [ClrAssembly](#).

# ColumnBinding Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents the binding of a column in a data source view to a [DataItem](#) element.

## Syntax

XML

```
<ColumnBinding>
 <!-- The following elements extend Binding -->
 <TableID>...</TableID>
 <ColumnID>...</ColumnID>
</ColumnBinding>
```

## Data Type Characteristics

[ ] Expand table

Characteristic	Description
Base data types	<a href="#">Binding</a>
Derived data types	None

## Data Type Relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">ColumnID</a> , <a href="#">TableID</a>
Derived elements	See <a href="#">Binding</a>

## Remarks

To create valid XML element names, ADO.NET **DataSet** objects encode table names as they serialize to XML Schema Definition (XSD); for example, the name "Order Details" becomes "Order\_x0020\_Details". Likewise, the **ColumnID** and **TableID** elements contained by the **ColumnBinding** element and which reference objects in the data source view (DSV) must also encode names during serialization, to ensure that the names directly match the text in the DSV. The Analysis Services instance will decode these names, just as the **DataSet** object model does.

A **TableDefinitions** element contained by an element using the **TableBinding** data type and which refers to tables in the DSV must also encode names as they serialize to XSD. However, the table names in the **Partition** bindings should not be encoded because these names are simply names of tables that exist in the database and do not have to be in the DSV. Not encoding the table names in the **Partition** bindings also achieves the following:

- It keeps the data definition library (DDL) for partitions simpler.
- It provides more consistency because partitions can either have a table name or a SELECT statement, and the SELECT statement should not be encoded.

Table and column names do not include delimiters (for example, "[" for).

For additional information about the **Binding** type, including tables of Analysis Services Scripting Language (ASSL) objects of the **Binding** type and the inheritance hierarchy of **Binding** types, see [Binding Data Type \(ASSL\)](#).

The corresponding element in the AMO object model is [ColumnBinding](#).

# ComAssembly Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a COM library associated with a [Server](#) or [Database](#) element.

## ⓘ Important

COM assemblies might pose a security risk. Due to this risk and other considerations, COM assemblies are deprecated.

## Syntax

### XML

```
<ComAssembly>
 <!-- The following elements extend Assembly -->
 <Source>...</Source>
</ComAssembly>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	<a href="#">Assembly</a>
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Source</a>

Relationship	Element
Derived elements	See <a href="#">Assembly (Assemblies collection of Database or Server)</a>

## Remarks

The **ComAssembly** element contains a reference (either the fully qualified file name or the programmatic identifier) to a COM library associated with an instance of Analysis Services or with a specific database on an instance.

The corresponding element in the Analysis Management Objects (AMO) object model is [ComAssembly](#).

 No

# CubeAttribute Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents an attribute associated with a [Cube](#) element.

## Syntax

XML

```
<CubeAttribute>
 <AttributeID>...</AttributeID>
 <AggregationUsage>...</AggregationUsage>
 <AttributeHierarchyOptimizedState>...</AttributeHierarchyOptimizedState>
 <AttributeHierarchyEnabled>...</AttributeHierarchyEnabled>
 <AttributeHierarchyVisible>...</AttributeHierarchyVisible>
 <Annotations>...</Annotations>
</CubeAttribute>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">AggregationUsage</a> , <a href="#">Annotations</a> , <a href="#">AttributeHierarchyEnabled</a> , <a href="#">AttributeHierarchyOptimizedState</a> , <a href="#">AttributeHierarchyVisible</a> , <a href="#">AttributeID</a>

Relationship	Element
Derived elements	<a href="#">Attribute (Attributes collection of CubeDimension)</a>

## Remarks

The *AttributeHierarchyOptimizedState* element is not supported when running the service in DeploymentMode configuration property values of 1 or 2 (SharePoint or Tabular modes, used to run Power Pivot and tabular model databases).

An attribute cannot be added as a level of a hierarchy when the property, *AttributeHierarchyEnabled*, is set to FALSE and the instance is operating under DeploymentMode 1 or 2 (SharePoint or Tabular server mode).

Attributes in the [CubeDimension](#) element that are not explicitly included in the [Attributes](#) collection become part of the collection with default values assigned to them. After attributes are added to the collection, the attributes can be returned by the [Discover](#) method.

The [AggregationUsage](#) element controls how Analysis Services automatically designs aggregations for the attribute. The [AggregationUsage](#) element does not constrain any aggregations that are manually created for the cube.

The corresponding element in the Analysis Management Objects (AMO) object model is [CubeAttribute](#).

# CubeDimension Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents the relationship between a dimension and a cube.

## Syntax

XML

```
<CubeDimension>
 <ID>...</ID>
 <Name>...</Name>
 <Translations>...</Translations>
 <DimensionID>...</DimensionID>
 <Visible>...</Visible>
 <AllMemberAggregationUsage>...</AllMemberAggregationUsage>
 <HierarchyUniqueNameStyle>...</HierarchyUniqueNameStyle>
 <MemberUniqueNameStyle>...</MemberUniqueNameStyle>
 <Attributes>...</Attributes>
 <Hierarchies>...</Hierarchies>
 <Annotations>...</Annotation>
</CubeDimension>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None

Relationship	Element
Child elements	<a href="#">AllMemberAggregationUsage</a> , <a href="#">Annotations</a> , <a href="#">Attributes</a> , <a href="#">DimensionID</a> , <a href="#">Hierarchies</a> , <a href="#">HierarchyUniqueNameStyle</a> , <a href="#">ID</a> , <a href="#">MemberUniqueNameStyle</a> , <a href="#">Name</a> , <a href="#">Visible</a> , <a href="#">Translations</a>
Derived elements	<a href="#">Dimension</a> ( <a href="#">Dimensions</a> collection of <a href="#">Cube</a> )

## Remarks

There is one **CubeDimension** for each dimension relationship on a **Cube**. The **CubeDimension** covers all the **MeasureGroups** of the cube.

A **CubeDimension** must include a [CubeHierarchy](#) if the dimension has something specific to say about the hierarchy, including disabling the hierarchy (thereby, allowing selection of which hierarchies apply to a particular dimension usage), or making the hierarchy invisible.

Similarly, a **CubeDimension** must include a [CubeAttribute](#) only if the dimension has something specific to say about the attribute. (There is no way to select which attributes apply to a particular dimension usage, though attributes can be made invisible).

The corresponding element in the Analysis Management Objects (AMO) object model is [CubeDimension](#).

# CubeDimensionBinding Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents the binding of a [Dimension](#), [Measure](#), or [MiningModel](#) element to a cube dimension.

## Syntax

XML

```
<CubeDimensionBinding>
 <!-- The following elements extend Binding -->
 <DataSourceID>...</DataSourceID>
 <CubeID>...</CubeID>
 <CubeDimensionID>...</CubeDimensionID>
 <Filter>...</Filter>
</CubeDimensionBinding>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	<a href="#">Binding</a>
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">CubeDimensionID</a> , <a href="#">CubeID</a> , <a href="#">DataSourceID</a> , <a href="#">Filter</a>
Derived elements	See <a href="#">Binding</a>

## Remarks

For additional information about the **Binding** type, including tables of Analysis Services Scripting Language (ASSL) objects of the **Binding** type and the inheritance hierarchy of **Binding** types, see [Binding Data Type \(ASSL\)](#).

The corresponding element in the Analysis Management Objects (AMO) object model is [CubeDimensionBinding](#).

# CubeDimensionPermission Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents the permissions for a single role on a specific dimension in a cube.

## Syntax

XML

```
<CubeDimensionPermission>
 <CubeDimensionID>...</CubeDimensionID>
 <Description>...</Description>
 <Read>...</Read>
 <Write>...</Write>
 <AttributePermissions>...</AttributePermissions>
 <Annotations>...</Annotations>
</CubeDimensionPermission>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

# CubeHierarchy Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a [Hierarchy](#) element in a [Cube](#) element.

## Syntax

XML

```
<CubeHierarchy> <HierarchyID>...</HierarchyID> <Name>...</Name>
<OptimizedState>...</OptimizedState> <Visible>...</Visible> <Enabled>...
</Enabled> <Annotations>...</Annotations></CubeHierarchy>
```

## Data Type Characteristics

[+] [Expand table](#)

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">Enabled</a> , <a href="#">HierarchyID</a> , <a href="#">Name</a> , <a href="#">OptimizedState</a> , <a href="#">Visible</a>
Derived elements	<a href="#">Hierarchy</a> ( <a href="#">Hierarchies</a> collection of <a href="#">CubeDimension</a> )

## Remarks

This data type has no restrictions and can be used under any deployment mode: 0-Multidimensional and Data Mining, 1-SharePoint, and 2-Tabular.

In SQL Server 2016 Analysis Services and later, the *Enabled* property cannot be set to **False** for *CubeHierarchy*.

The corresponding element in the Analysis Management Objects (AMO) object model is [CubeHierarchy](#).

# DataItem Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents the data-related characteristics of a data item, such as a column or attribute.

## Syntax

XML

```
<DataItem>
 <DataType>...</DataType>
 <DataSize>...</DataSize>
 <MimeType>...</MimeType>
 <NullProcessing>...</NullProcessing>
 <Trimming>...</Trimming>
 <InvalidXmlCharacters>...</InvalidXmlCharacters>
 <Collation>...</Collation>
 <Format>...</Format>
 <Source>...</Source>
 <Annotations>...</Annotations>
</DataItem>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None

Relationship	Element
Child elements	<a href="#">Annotations</a> , <a href="#">Collation</a> , <a href="#">DataSize</a> , <a href="#">DataType</a> , <a href="#">Format</a> , <a href="#">InvalidXmlCharacters</a> , <a href="#">MimeType</a> , <a href="#">NullProcessing</a> , <a href="#">Source</a> , <a href="#">Trimming</a>
Derived elements	See the table in Remarks.

## Remarks

The **DataItem** data type is used for any data item that can be bound; for example, a measure, attribute key, and attribute name. The details that are relevant, and the defaults that apply, depend on the usage; for example, attribute names must be strings.

An instance of Analysis Services accepts only a certain set of data types. Use of other data types results in an error, rather than an implicit conversion to one of the valid types.

The following table lists elements of type **DataItem**.

[\[+\] Expand table](#)

Parent Element	Element of type DataItem	Comments
<a href="#">AttributeTranslation</a>	<a href="#">CaptionColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
<a href="#">DimensionAttribute</a>	<a href="#">CustomRollupColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
<a href="#">DimensionAttribute</a>	<a href="#">CustomRollupPropertiesColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
<a href="#">DimensionAttribute</a>	<a href="#">KeyColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> , <a href="#">AttributeBinding</a> or <a href="#">TimeBinding</a>
<a href="#">DimensionAttribute</a>	<a href="#">NameColumn</a>	Source element of the <b>DataItem</b> must be of type

Parent Element	Element of type DataItem	Comments
		<a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
DimensionAttribute	<a href="#">SkippedLevelsColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
DimensionAttribute	<a href="#">UnaryOperatorColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> or <a href="#">AttributeBinding</a>
Measure	<a href="#">Source</a>	Source element of the <b>DataItem</b> must be of type <a href="#">RowBinding</a> , <a href="#">ColumnBinding</a> , <a href="#">MeasureBinding</a> , or <a href="#">CubeDimensionBinding</a>
MeasureGroupAttribute	<a href="#">KeyColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a> , <a href="#">AttributeBinding</a> or <a href="#">InheritedBinding</a>
ScalarMiningStructureColumn	<a href="#">KeyColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a>
ScalarMiningStructureColumn	<a href="#">NameColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a>
TableMiningStructureColumn	<a href="#">ForeignKeyColumn</a>	Source element of the <b>DataItem</b> must be of type <a href="#">ColumnBinding</a>

The corresponding element in the Analysis Management Objects (AMO) object model is [DataItem](#).

 Yes

 No

# DataSource Data Type (ASSL)

Article • 10/31/2023

Defines an abstract primitive data type that represents a data source in a [Database](#) element.

## Syntax

XML

```
<DataSource>
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <ManagedProvider>...</ManagedProvider>
 <ConnectionString>...</ConnectionString>
 <ConnectionStringSecurity>...</ConnectionStringSecurity>
 <ImpersonationInfo>...</ImpersonationInfo>
 <Isolation>...</Isolation>
 <MaxActiveConnections>...</MaxActiveConnections>
 <Description>...</Description>
 <Timeout>...</Timeout>
 <Annotations>...</Annotations>
 <DataSourcePermission>...</DataSourcePermission>
</DataSource>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	<a href="#">RelationalDataSource</a> , <a href="#">OlapDataSource</a> , <a href="#">PushedDataSource</a>

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">ConnectionString</a> , <a href="#">ConnectionStringSecurity</a> , <a href="#">CreatedTimestamp</a> , <a href="#">DataSourcePermission</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">ImpersonationInfo</a> , <a href="#">Isolation</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">ManagedProvider</a> , <a href="#">MaxActiveConnections</a> , <a href="#">Name</a> , <a href="#">Timeout</a>
Derived elements	None

## Remarks

When defining out-of-line bindings, the **Name** element is optional. Not having to specify a **Name** element allows data sources to be defined within the binding for cubes, partitions, and so on. For data sources contained by a **Database** element, **Name** is a required element.

The corresponding element in the Analysis Management Objects (AMO) object model is [DataSource](#).

 <InstanceSelection>...</InstanceSelection>
 <Annotations>...</Annotations>
</DimensionAttribute>
```

# Data Type Characteristics

[+] [Expand table](#)

Characteristic	Description
Base data types	None
Derived data types	None

# Data Type Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	Annotations, AttributeHierarchyDisplayFolder, AttributeHierarchyEnabled, AttributeHierarchyOptimizedState, AttributeHierarchyOrdered, AttributeHierarchyVisible, AttributeRelationships, CustomRollupColumn, CustomRollupPropertiesColumn, DefaultMember, Description, DiscretizationBucketCount, DiscretizationMethod, EstimatedCount, ID, InstanceSelection, IsAggregatable, KeyColumns, KeyUniquenessGuarantee, MemberNamesUnique, MembersWithData, MembersWithDataCaption, Name, NameColumn, NamingTemplate, NamingTemplateTranslations, OrderBy, OrderByAttributeID, RootMemberIf, SkippedLevelsColumn, Source, Translations, Type, UnaryOperatorColumn, Usage, ValueColumn
Derived elements	<a href="#">Attribute (Attributes collection of Dimension)</a>

# Remarks

The following restrictions apply when running the service in DeploymentMode configuration property values of 1 and 2 (SharePoint and Tabular modes, used to run Power Pivot and tabular model databases):

- Usage element only accepts KEY or REGULAR values.
- IsAggregatable element cannot be false.
- OrderBy element only accepts KEY or PROPERTYKEY values.

- A calculated column cannot be a primary key in the table.
- A calculated column cannot contain DataSize in the binding.
- For each calculated column a syntax validation is performed before saving the attribute definition.
- For AttributeRelationships, RelationshipType must be set to the value, Flexible.
- The attribute 'RowNumber', identified by 'RowNumber', must have the type integer.
- Only the attribute 'RowNumber' can have KeyBinding of type RowNumberBinding.
- All attributes other than 'RowNumber' must have a Cardinality of one in relation to the key, unless the attribute itself is the key.
- When the column specified by OrderBy is also the PropertyKey, the OrderByAttributId cannot point to the row number column.
- Attributes used as keys should be related to all other attributes; other types of relationships are not supported.
- The NullProcessing element cannot be set to 'UnknownMember'.
- Bindings cannot be set to 'Value'.

The following elements are unsupported when running the service in DeploymentMode configuration property values of 1 and 2 (SharePoint and Tabular modes, used to run Power Pivot and tabular model databases):

- AttributeHierarchyOptimizedState
- CustomRollupColumn
- CustomRollupPropertiesColumn
- DefaultMember
- DiscretizationBucketCount
- DiscretizationMethod
- SkippedLevelsColumn
- Source
- UnaryOperatorColumn

The corresponding element in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

Derived elements	<a href="#">Dimension</a> ( <a href="#">Dimensions</a> collection of <a href="#">MeasureGroup</a> )

# Remarks

Each **MeasureGroupDimension** is a reference to one of the dimensions on the cube. These define which cube dimensions apply to the measure group.

The set of attributes that are provided determines the granularity (scope) at which the measures on the measure group are known. For example, measures that represent product sales are contained in the Sales measure group. Information for these measures is stored in the underlying data source on a monthly, rather than weekly or daily, granularity. In this case, only the Month attribute would be listed for the **MeasureGroupDimension** that describes the relationship between a time dimension and the Sales measure group. In rare cases, the granularity might be defined in terms of a set of attributes. For example, given the set of attributes {Day, Week, Month, Year}, where Day implies Week and Month, but Week does not imply Month, the measures contained in the Forecasts measure group might be known by Month and Week, but not by Day.

If no attribute is provided, it is as if only the key attribute for the dimension were listed (defining the lowest level of granularity). Each partition of a measure group must have the same granularity. The set of attributes listed should not be redundant with respect to the relationships between attributes. For example, if Month implies Year, the granularity is defined as Month, not Month and Year.

A **MeasureGroupDimension** needs to include a hierarchy only if it has something specific to indicate about it. (There is no way to select which hierarchies apply to a particular measure group). Similarly, it needs to include a **MeasureGroupAttribute** only if it has something specific to indicate about it.

Each hierarchy must be a subset of the hierarchies included on the **CubeDimension**. It is not possible to select the levels, though some levels might automatically be disabled depending upon the granularity of the measure group.

The corresponding element in the Analysis Management Objects (AMO) object model is [MeasureGroupDimension](#).

# MiningModelingFlag Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents the available modeling flags for a [ModelingFlag](#) element.

## Syntax

XML

```
<MiningModelingFlag>...</MiningModelingFlag>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	String (enumeration)
Derived data types	None

## Data Type Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	None
Derived elements	<a href="#">ModelingFlag</a> ( <a href="#">ModelingFlags</a> collection of <a href="#">MiningModelColumn</a> or <a href="#">ScalarMiningStructureColumn</a> )

## Remarks

The flag name may contain spaces. The natively-supported values are listed in the following table.

Value	Description
<i>MODEL_EXISTENCE_ONLY</i>	The column should be modeled as having two states, missing and nonmissing, regardless of the values in the column. This is particularly useful for columns in a nested table, where values are sparse across cases.
<i>NOT NULL</i>	The column cannot accept NULL values.
<i>REGRESSOR</i>	The column supplies regressor values for test cases.

Additional provider-specific flags may be used if third-party OLE DB or data mining providers have been aggregated on the instance of Analysis Services.

A closely related element in the Analysis Management Objects (AMO) object model is [MiningModelingFlags](#).

# Permission Data Type (ASSL)

Article • 10/31/2023

Defines an abstract primitive data type that represents information about an individual permission.

## Syntax

XML

```
<Permission>
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <RoleID>...</RoleID>
 <Description>...</Description>
 <Process>...</Process>
 <ReadDefinition>...</ReadDefinition>
 <Read>...</Read>
 <Write>...</Write>
 <Annotations>...</Annotations>
</Permission>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	<a href="#">CubePermission</a> , <a href="#">DatabasePermission</a> , <a href="#">DimensionPermission</a> , <a href="#">MiningModelPermission</a> , <a href="#">MiningStructurePermission</a>

## Data Type Relationships

[+] Expand table

<b>Relationship</b>	<b>Element</b>
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">CreatedTimestamp</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">Name</a> , <a href="#">Process</a> , <a href="#">Read</a> , <a href="#">ReadDefinition</a> , <a href="#">RoleID</a> , <a href="#">Write</a>
Derived elements	None

## Remarks

**Permission** serves as the abstract base type for a number of derived permission types used in an instance of Analysis Services.

This data type has the following validations under DeploymentMode value 2 (tabular server mode).

- *Process* attribute default value is set to **False**, except when the user has the **Refresh** permission. For users with the **Refresh** permission the *Process* attribute value is set to **True**.
- *ReadDefinition* attribute value is set to **None**; any other value generates an error.
- *Read* attribute value is set to **Allowed** for users with the **User** permission and to **None** when the users are assigned to the **Refresh** permission; if a user has both **User** and **Refresh** permissions, then the attribute is set to **Allowed**. For users with administrative privileges the attribute value is set to **Allowed**.
- *Write* attribute value is set to **None**; any other value generates an error.

The corresponding element in the Analysis Management Objects (AMO) object model is [Permission](#).

# PerspectiveDimension Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a dimension in a perspective.

## Syntax

XML

```
<PerspectiveDimension>
 <CubeDimensionID>...</CubeDimensionID>
 <Attributes>...</Attributes>
 <Hierarchies>...</Hierarchies>
 <Annotations>...</Annotations>
</PerspectiveDimension>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">Attributes</a> , <a href="#">CubeDimensionID</a> , <a href="#">Hierarchies</a>
Derived elements	<a href="#">Dimension</a> ( <a href="#">Dimensions</a> collection of <a href="#">Perspective</a> )

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveDimension](#).

 No

# PerspectiveHierarchy Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a hierarchy in a [PerspectiveDimension](#) element.

## Syntax

XML

```
<PerspectiveHierarchy>
 <HierarchyID>...</HierarchyID>
 <Annotations>...</Annotations>
</PerspectiveHierarchy>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">HierarchyID</a>
Derived elements	<a href="#">Hierarchy</a> ( <a href="#">Hierarchies</a> collection of <a href="#">PerspectiveDimension</a> )

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveHierarchy](#).

# PerspectiveKpi Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a key performance indicator (KPI) in a [Perspective](#) element.

## Syntax

XML

```
<PerspectiveKpi>
 <KpiID>...</KpiID>
 <Annotations>...</Annotations>
</PerspectiveKpi>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">KpiID</a>
Derived elements	<a href="#">Kpi</a> ( <a href="#">Kpis</a> collection of <a href="#">Perspective</a> )

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveKpi](#).

# PerspectiveMeasure Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a measure in a [PerspectiveMeasureGroup](#) element.

## Syntax

XML

```
<PerspectiveMeasure>
 <MeasureID>...</MeasureID>
 <Annotations>...</Annotations>
</PerspectiveMeasure>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">MeasureID</a>
Derived elements	<a href="#">Measure</a> ( <a href="#">Measures</a> collection of <a href="#">PerspectiveMeasureGroup</a> )

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveMeasure](#).

 No

# PerspectiveMeasureGroup Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents information about a measure group in a [Perspective](#) element.

## Syntax

XML

```
<PerspectiveMeasureGroup>
 <MeasureGroupID>...</MeasureGroupID>
 <Measures>...</Measures>
 <Annotations>...</Annotations>
</PerspectiveMeasureGroup>
```

## Data Type Characteristics

[ ] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Annotations</a> , <a href="#">MeasureGroupID</a> , <a href="#">Measures</a>
Derived elements	<a href="#">MeasureGroup</a> ( <a href="#">MeasureGroups</a> collection of <a href="#">Perspective</a> )

## Remarks

A measure group in a perspective has the same structure as a measure group in the underlying cube.

The corresponding element in the Analysis Management Objects (AMO) object model is [PerspectiveMeasureGroup](#).

# ProactiveCachingBinding Data Type (ASSL)

Article • 10/31/2023

Defines an abstract derived data type that represents information to the [ProactiveCaching](#) element about data source changes that require rebuilding the cache, or about the status of the rebuilding process.

## Syntax

XML

```
<ProactiveCachingBinding>
 <!-- ProactiveCachingBinding is an abstract base class with no child
elements -->
</ProactiveCachingBinding>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	<a href="#">Binding</a>
Derived data types	<a href="#">ProactiveCachingIncrementalProcessingBinding</a> , <a href="#">ProactiveCachingObjectNotificationBinding</a> , <a href="#">ProactiveCachingQueryBinding</a>

## Data Type Relationships

# ProactiveCachingIncrementalProcessingBinding Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a binding to the [ProactiveCaching](#) element about the status of the process of rebuilding the cache.

## Syntax

XML

```
<ProactiveCachingIncrementalProcessingBinding>
 <!-- The following elements extend ProactiveCachingBinding -->
 <RefreshInterval>...</ RefreshInterval >
 <IncrementalProcessingNotification>...</
 IncrementalProcessingNotification >
</ProactiveCachingIncrementalProcessingBinding>
```

## Data Type Characteristics

# ProactiveCachingObjectNotificationBinding Data Type (ASSL)

Article • 10/31/2023

Defines an abstract derived data type that represents information to the [ProactiveCaching](#) element about data source changes, either in specified tables and views or in tables and views identified through existing data bindings that require rebuilding the cache.

## Syntax

XML

```
<ProactiveCachingObjectNotificationBinding>
 <!-- The following elements extend ProactiveCachingBinding -->
 <NotificationTechnique>...</NotificationTechnique>
</ProactiveCachingObjectNotificationBinding>
```

## Data Type Characteristics

[ ] [Expand table](#)

Characteristic	Description
Base data types	<a href="#">ProactiveCachingBinding</a>
Derived data types	<a href="#">ProactiveCachingInheritedBinding</a> , <a href="#">ProactiveCachingTablesBinding</a>

# ProactiveCachingQueryBinding Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents information to the [ProactiveCaching](#) element about data source changes in tables and views, identified through the execution of the specified queries that require rebuilding the cache.

## Syntax

XML

```
<ProactiveCachingQueryBinding>
 <!-- The following elements extend ProactiveCachingBinding -->
 <RefreshInterval>...</RefreshInterval>
 <QueryNotification>...</QueryNotification>
</ProactiveCachingQueryBinding>
```

## Data Type Characteristics

# PushedDataSource Data Type (ASSL)

Article • 10/31/2023

Defines a primitive data type that represents a data source used for "pushing" data into a [Cube](#) element.

## Syntax

XML

```
<PushedDataSource>
 <Root>...</Root>
 <EndOfData>...</EndOfData>
</PushedDataSource>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	None
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">EndOfData</a> , <a href="#">Root</a>
Derived elements	None

## Remarks

**PushedDataSource** is used only within a processing command as an out-of-line data source. Persisted data sources are never of this type.

# ReferenceMeasureGroupDimension Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a dimension that is indirectly related to the fact table through an intermediate dimension. (For example, a Sales measure group can reference a Geography dimension, which is related through the Customer dimension.)

## Syntax

XML

```
<ReferenceMeasureGroupDimension>
 <!-- The following elements extend MeasureGroupDimension -->
 <IntermediateCubeDimensionID>...</IntermediateCubeDimensionID>
 <IntermediateGranularityAttributeID>...
</IntermediateGranularityAttributeID>
 <Materialization>...</Materialization>
</ReferenceMeasureGroupDimension>
```

## Data Type Characteristics

# ReportAction Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents an action that generates a Reporting Service report.

## Syntax

XML

```
<ReportAction>
 <!-- The following elements extend Action -->
 <ReportServer>...</ReportServer>
 <Path>...</Path>
 <ReportParameters>...</ReportParameters>
 <ReportFormatParameters>...</ReportFormatParameters>
</ReportAction>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	Action
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	Path, ReportFormatParameters, ReportParameters, ReportServer
Derived elements	Action ( <a href="#">Actions collection of Cube or Perspective</a> )

## Remarks

The report server responds to URL-based requests for reports. The report action is defined with a type *Report*. The resources and parameters are sent to the server when the action is created. The server exposes the action as an action of type rowset.

The corresponding element in the Analysis Management Objects (AMO) object model is [ReportAction](#).

# ScalarMiningStructureColumn Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a [MiningStructureColumn](#) element that contains scalar values, as opposed to the nested tables associated with the [TableMiningStructureColumn](#) element that contains nested tables.

## Syntax

XML

```
<ScalarMiningStructureColumn>
 <!-- The following elements extend MiningStructureColumn -->
 <IsKey>...</IsKey>
 <Source>...</Source>
 <Distribution>...</Distribution>
 <ModelingFlags>...</ModelingFlags>
 <Content>...</Content>
 <ClassifiedColumnID>...</ClassifiedColumnI
 <DiscretizationMethod>...</DiscretizationMethod>
 <DiscretizationBucketCount>...</DiscretizationBucketCount>
 <KeyColumns>...</KeyColumns>
 <NameColumn>...</NameColumn>
 <Translations>...</Translations>
</ScalarMiningStructureColumn>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	<a href="#">MiningStructureColumn</a>
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element

## Feedback

Was this page helpful?

 Yes

 No

# TableBinding Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a binding to a table.

## Syntax

XML

```
<TableBinding>
 <!-- The following elements extend TabularBinding -->
 <DataSourceID>...</DataSourceID>
 <DbTableName>...</DbTableName>
 <DbSchemaName>...</DbSchemaName>
</TableBinding>
```

## Data Type Characteristics

[+] Expand table

Characteristic	Description
Base data types	TabularBinding
Derived data types	None

## Data Type Relationships

[+] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">DataSourceID</a> , <a href="#">DbSchemaName</a> , <a href="#">DbTableName</a>
Derived elements	See <a href="#">Binding</a>

## Remarks

Note that referencing other tables in the filter expression by use of a subselect could have performance implications in some data sources. However, the designer can totally control the SQL expression by defining a named query in the data source view, and then referencing that.

The method of defining the bindings for a partition are independent of the use of partitioned tables in the data source view.

As an example, consider a measure group whose default table is "Sales," with columns Date, Product ID, Qty, Price, and Amount (calculated in the data source view). Then the partition "Sales97" could use the table "Sales97" with filter "Year(Sales.Date) = 97."

The effective query is:

SQL

```
SELECT Date, Product ID, Qty, Price, Qty * Price AS Amount
FROM Sales97 As Sales
WHERE Year(Sales.Date) = 97
```

The calculated expression still applies, even if the expression used qualified table names (for example, Sales.Qty). The same applies if instead the table were replaced by some query "SELECT..." The FROM clause above would become "FROM SELECT ... As Sales."

For more information about the **Binding** type, including tables of Analysis Services Scripting Language (ASSL) objects of type **Binding** and the inheritance hierarchy of **Binding** types, see [Binding Data Type \(ASSL\)](#).

The corresponding element in the Analysis Management Objects (AMO) object model is [TableBinding](#).

# TableMiningStructureColumn Data Type (ASSL)

Article • 10/31/2023

Defines a derived data type that represents a [MiningStructureColumn](#) element that contains nested tables, as opposed to the scalar values associated with the [ScalarMiningStructureColumn](#) element that contains scalar values.

## Syntax

XML

```
<TableMiningStructureColumn>
 <!-- The following elements extend MiningStructureColumn -->
 <ForeignKeyColumn>..</ForeignKeyColumn>
 <SourceMeasureGroup>..</SourceMeasureGroup>
 <Columns>..</Columns>
 <Translations>..</Translations>
</TableMiningStructureColumn>
```

## Data Type Characteristics

[ ] Expand table

Characteristic	Description
Base data types	<a href="#">MiningStructureColumn</a>
Derived data types	None

## Data Type Relationships

[ ] Expand table

Relationship	Element
Parent elements	None
Child elements	<a href="#">Columns</a> , <a href="#">ForeignKeyColumn</a> , <a href="#">SourceMeasureGroup</a> , <a href="#">Translations</a>

Relationship	Element
Derived elements	<a href="#">Column (Columns collection of MiningStructure)</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [TableMiningStructureColumn](#).

# Objects (ASSL)

Article • 10/31/2023

This reference section contains syntax and usage information for each element that acts as an object in the Analysis Services Scripting Language (ASSL) schema.

Although the ASSL schema contains only XML elements, from a developer's point of view, the elements described in this section correspond to objects, such as **Database**, **Cube**, and **Dimension** objects, in the hierarchy of objects contained by an instance of Analysis Services.

Objects are never leaf-level elements in the ASSL schema, but have child elements and elements that correspond to object properties.

In a few cases, a leaf-level element in the schema that may appear to be a property is classified as an object because the element's type is an object type. For example, the **Source** of a **Dimension** object is of type **DimensionBinding**.

## In This Section

[ ] [Expand table](#)

Element	Description
<a href="#">Account Element (ASSL)</a>	Contains details about an account type within a <a href="#">Database</a> element.
<a href="#">Action Element (ASSL)</a>	Contains information about an action available in a <a href="#">Cube</a> element or a <a href="#">Perspective</a> element.
<a href="#">Aggregation Element (ASSL)</a>	Defines a single aggregation for a <a href="#">Partition</a> element.
<a href="#">AggregationDesign Element (ASSL)</a>	Defines a set of aggregation definitions that can be shared across multiple partitions in a database.
<a href="#">AggregationInstance Element (ASSL)</a>	Defines an aggregation instance for a partition.
<a href="#">AlgorithmParameter Element (ASSL)</a>	Defines a parameter for the algorithm used by a <a href="#">MiningModel</a> element.
<a href="#">AllMemberTranslation Element (ASSL)</a>	Contains a translation for the caption of the All member of a <a href="#">Hierarchy</a> element.
<a href="#">Annotation Element (ASSL)</a>	Contains elements that are used to extend the ASSL schema.

Element	Description
<a href="#">Assembly Element (ASSL)</a>	Represents a Microsoft .NET Framework assembly or a COM dynamic link library (DLL) associated with a <a href="#">Server</a> element or a <a href="#">Database</a> element.
<a href="#">Attribute Element (ASSL)</a>	Contains the description of an attribute.
<a href="#">AttributeAllMemberTranslation Element (ASSL)</a>	Contains a translation for the caption of the All member of a <a href="#">DimensionAttribute</a> element.
<a href="#">AttributePermission Element (ASSL)</a>	Defines the permissions that members of a <a href="#">Role</a> element have on the attributes of an individual dimension in a <a href="#">Cube</a> element.
<a href="#">AttributeRelationship Element (ASSL)</a>	Provides details about the relationship between two attributes.
<a href="#">Block Element (ASSL)</a>	Contains all or a portion of the binary contents of a <a href="#">ClrAssemblyFile</a> element.
<a href="#">Calculation Element (ASSL)</a>	Associates a calculation with a <a href="#">Perspective</a> element.
<a href="#">CalculationProperty Element (ASSL)</a>	Contains a collection of user interface properties for a calculation used in an <a href="#">MdxScript</a> element.
<a href="#">CaptionColumn Element (ASSL)</a>	Defines the column that provides the caption for the attribute.
<a href="#">CellPermission Element (ASSL)</a>	Describes the permissions that members of a <a href="#">Role</a> element have on individual cells within a <a href="#">Cube</a> element.
<a href="#">Column Element (ASSL)</a>	Describes a column in the collection of columns associated with the parent element.
<a href="#">Command Element (ASSL)</a>	Defines a command that is available for use within the context of the parent element of the Commands collection.
<a href="#">Cube Element (ASSL)</a>	Defines a regular, virtual, or linked cube in an Analysis Services <a href="#">Database</a> element.
<a href="#">CubePermission Element (ASSL)</a>	Defines the permissions of the members of a particular <a href="#">Role</a> element in a specific <a href="#">Cube</a> element.
<a href="#">CustomRollupColumn Element (ASSL)</a>	Defines the details of the column that provide a custom rollup formula.
<a href="#">CustomRollupPropertiesColumn Element (ASSL)</a>	Defines the details of a column that provide the properties of a custom rollup formula.

Element	Description
<a href="#">Data Element (ASSL)</a>	Contains (in the collection of child <b>Block</b> elements) the binary contents of a <a href="#">ClrAssemblyFile</a> element.
<a href="#">Database Element (ASSL)</a>	Defines an Analysis Services database.
<a href="#">DatabasePermission Element (ASSL)</a>	Defines the default permissions in a <a href="#">Database</a> element for a specific <a href="#">Role</a> element.
<a href="#">DataSource Element (ASSL)</a>	Defines a data source in a <a href="#">Database</a> element.
<a href="#">DataSourcePermission Element (ASSL)</a>	Defines the default permissions in a <a href="#">DataSource</a> data type for a specific <a href="#">Role</a> element.
<a href="#">DataSourceView Element (ASSL)</a>	Defines a data source view used by a <a href="#">Database</a> element.
<a href="#">Dimension Element (ASSL)</a>	Defines a dimension.
<a href="#">DimensionPermission Element (ASSL)</a>	Defines the permissions that belong to a particular <a href="#">Role</a> element for a specific database dimension or cube dimension.
<a href="#">ErrorConfiguration Element (ASSL)</a>	Specifies settings for handling errors that can occur when the parent element is processed.
<a href="#">Event Element (ASSL)</a>	Defines an event to be captured as part of a <a href="#">Trace</a> element.
<a href="#">File Element (ASSL)</a>	Defines one of the files that compose a <a href="#">ClrAssembly</a> element.
<a href="#">ForeignKeyColumn Element (ASSL)</a>	Identifies the join to a parent table for a relational data source.
<a href="#">Group Element (ASSL)</a>	Defines a group of members bound to an attribute.
<a href="#">Hierarchy Element (ASSL)</a>	Defines a hierarchy in a dimension.
<a href="#">IncrementalProcessingNotification Element (ASSL)</a>	Contains information for the <a href="#">ProactiveCaching</a> element about a query to execute to determine the progress of incremental processing.
<a href="#">KeyColumn Element (ASSL)</a>	Contains the definition of a column that is, or is part of, the key for an attribute.
<a href="#">Kpi Element (ASSL)</a>	Defines a key performance indicator (KPI) within a <a href="#">Cube</a> element or a <a href="#">Perspective</a> element.
<a href="#">Level Element (ASSL)</a>	Defines a level in a <a href="#">Hierarchy</a> element.
<a href="#">MdxScript Element (ASSL)</a>	Contains information about a Multidimensional Expressions (MDX) script that is associated with a <a href="#">Cube</a>

Element	Description
	element.
<a href="#">Measure Element (ASSL)</a>	Defines a measure.
<a href="#">MeasureGroup Element (ASSL)</a>	Defines a set of measures at the same level of granularity.
<a href="#">Member Element (ASSL)</a>	Contains the name of a member of a <a href="#">Group</a> element or of a <a href="#">Role</a> element.
<a href="#">MiningModel Element (ASSL)</a>	Defines a single data mining model.
<a href="#">MiningModelPermission Element (ASSL)</a>	Defines the permissions members of a <a href="#">Role</a> element have on an individual <a href="#">MiningModel</a> element.
<a href="#">MiningStructure Element (ASSL)</a>	Defines the structure for a set of mining models.
<a href="#">MiningStructurePermission Element (ASSL)</a>	Defines the permissions that members of a <a href="#">Role</a> element have on an individual <a href="#">MiningStructure</a> element.
<a href="#">ModelingFlag Element (ASSL)</a>	Contains a modeling flag for a column in a mining structure or a mining model.
<a href="#">NameColumn Element (ASSL)</a>	Identifies the column that provides the name of the parent element.
<a href="#">NamingTemplateTranslation Element (ASSL)</a>	Provides a localized translation of the <a href="#">NamingTemplate</a> element for a parent <a href="#">DimensionAttribute</a> data type.
<a href="#">Partition Element (ASSL)</a>	Defines a partition of a <a href="#">MeasureGroup</a> element or a partition binding in an out-of-line <a href="#">MeasureGroupBinding</a> element.
<a href="#">Perspective Element (ASSL)</a>	Defines details for a perspective of a <a href="#">Cube</a> element.
<a href="#">ProactiveCaching Element (ASSL)</a>	Defines proactive caching settings for the parent element.
<a href="#">QueryNotification Element (ASSL)</a>	Contains information for the <a href="#">ProactiveCaching</a> element about a query to execute to determine whether a data source has been modified.
<a href="#">ReportFormatParameter Element (ASSL)</a>	Contains the name and value of a parameter that specifies how a Reporting Service report is formatted at run time.
<a href="#">ReportParameter Element (ASSL)</a>	Contains the name and value of a parameter that is passed to a Reporting Service report at run time.
<a href="#">Role Element (ASSL)</a>	Contains information about a security role.
<a href="#">Server Element (ASSL)</a>	Describes an instance of Analysis Services.

Element	Description
<a href="#">ServerProperty Element (ASSL)</a>	Defines a server property associated with a <a href="#">Server</a> element.
<a href="#">SkippedLevelsColumn Element (ASSL)</a>	Provides the details of a column that stores the number of skipped (empty) levels between each member and its parent.
<a href="#">SourceMeasureGroup Element (ASSL)</a>	Identifies the measure group that serves as the data source for a mining structure column.
<a href="#">TableNotification Element (ASSL)</a>	Contains information for the <a href="#">ProactiveCaching</a> element about a table or view in a data source that has been modified.
<a href="#">Trace Element (ASSL)</a>	Defines a trace that can be queried.
<a href="#">Translation Element (ASSL)</a>	Provides a localized translation for the parent of the <a href="#">Translations</a> collection.
<a href="#">UnaryOperatorColumn Element (ASSL)</a>	Defines the details of a column providing a unary operator.
<a href="#">UnknownMemberTranslation Element (ASSL)</a>	Contains a translation for the caption of the <a href="#">UnknownMember</a> element for a <a href="#">Dimension</a> element.
<a href="#">ValueColumn Element (ASSL)</a>	Identifies the column that provides the value of the parent element.

## Feedback

 No

# Account Element (ASSL)

Article • 10/31/2023

Contains details about an account type within a [Database](#) element.

## Syntax

XML

```
<Accounts>
 <Account>
 <AccountType>...</AccountType>
 <AggregationFunction>...</AggregationFunction>
 <Aliases>...</Aliases>
 <Annotations>...</Annotations>
 </Account>
</Accounts>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Accounts</a>
Child elements	<a href="#">AccountType</a> , <a href="#">AggregationFunction</a> , <a href="#">Aliases</a> , <a href="#">Annotations</a>

## Remarks

Dimensions, whose [Type](#) element is set to *Accounts*, can have an attribute that specifies the account type, such as Income, Expense, and so on, represented by members in the dimension. The account type is then used by [Measure](#) elements, whose [AggregationFunction](#) element is set to *ByAccount*, to determine the aggregation function to use when aggregating the members of that dimension. The [Account](#) element represents a single account type and the aggregation function that should be used by such measures.

An account type must be listed if the aggregate function is different from the default used by Analysis Services for each account type.

The set of valid account types is fixed.

The corresponding element in the Analysis Management Objects (AMO) object model is [Account](#).

# AggregationInstance Element (ASSL)

Article • 10/31/2023

Defines an aggregation instance for a partition.

## Syntax

XML

```
<AggregationInstances>
 <AggregationInstance>
 <AggregationType>...</AggregationType>
 <AggregationID>...</AggregationID>
 <Source>...</Source>
 <Dimensions>...</Dimensions>
 <Measures>...</Measures>
 <Annotations>...</Annotations>
 </AggregationInstance>
</AggregationInstances>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">AggregationInstances</a>
Child elements	<a href="#">AggregationID</a> , <a href="#">AggregationType</a> , <a href="#">Annotations</a> , <a href="#">Dimensions</a> , <a href="#">Measures</a> , <a href="#">Source</a>

## Remarks

When a [Partition](#) element uses an [AggregationDesign](#) element to generate aggregations for that partition, each [Aggregation](#) in the [AggregationDesign](#) is instantiated for that partition. Multiple partitions can use the same aggregation design to generate multiple instances of a defined aggregation. The [AggregationInstance](#) element represents an instance of a defined aggregation.

The corresponding element in the Analysis Management Objects (AMO) object model is [AggregationInstance](#).

# AlgorithmParameter Element (ASSL)

Article • 10/31/2023

Defines a parameter for the algorithm used by a [MiningModel](#) element.

## Syntax

XML

```
<AlgorithmParameters>
 <AlgorithmParameter>
 <Name>...</Name>
 <Value>...</Value>
 </AlgorithmParameter>
</AlgorithmParameters>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">AlgorithmParameters</a>
Child elements	<a href="#">Name</a> , <a href="#">Value</a>

## Remarks

An **AlgorithmParameter** is a parameter for a mining model algorithm. The **AlgorithmParameter** represents this parameter as a name/value pair. The set of applicable parameters that an **AlgorithmParameter** can represent is algorithm-dependent. For more information about algorithm parameters for a given algorithm, see the appropriate documentation for that algorithm.

Available algorithm parameters, including validation and display information, can be retrieved from the `DMSCHEMA_MINING_SERVICE_PARAMETERS` schema rowset.

The corresponding element in the Analysis Management Objects (AMO) object model is [AlgorithmParameter](#).

# Annotation Element (ASSL)

Article • 10/31/2023

Contains elements that are used to extend the Analysis Services Scripting Language (ASSL) schema.

## Syntax

XML

```
<Annotations>
 <Annotation>
 <Name>...</Name>
 <Visibility>...</Visibility>
 <Value>...</Value>
 </Annotation>
</Annotations >
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	Annotations
Child elements	Name, Value, Visibility

## Remarks

The **Annotation** element provides extensibility of the ASSL schema for all objects other than those used solely to define a complex data type. The **Value** element of the **Annotation** element can contain valid XML from any XML namespace other than ASSL, subject to the following rules:

- The XML can contain only elements.
- Each element must have a unique name. It is recommended that the value of the **Name** element of the **Annotation** element reference the target namespace.

These rules are imposed to allow the contents of the **Annotation** element to be exposed as a set of name/value pairs through other interfaces, such as Decision Support Objects (DSO).

Comments and white space within the **Annotation** element that are not enclosed within a child element cannot be preserved. In addition, all elements must be read-write; read-only elements will be ignored.

The corresponding element in the Analysis Management Objects (AMO) object model is [Annotation](#).

# Assembly Element (ASSL)

Article • 10/31/2023

Represents a Microsoft .NET Framework assembly or a COM dynamic link library (DLL) associated with a [Server](#) element or a [Database](#) element.

## Syntax

XML

```
<Assemblies>
 <Assembly xsi:type="ClrAssembly">...</Assembly>
 <!-- or -->
 <Assembly xsi:type="ComAssembly">...</Assembly>
</Assemblies>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	<a href="#">ClrAssembly</a> , <a href="#">ComAssembly</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Assemblies</a>
Child elements	None

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [Assembly](#).

# Attribute Element (ASSL)

Article • 10/31/2023

Contains the description of an attribute.

## Syntax

XML

```
<Attributes>
 <Attribute xsi:type="AggregationAttribute">...</Attribute> <!-- ancestor:
AggregationDimension -->
 <!-- or -->
 <Attribute xsi:type="AggregationDesignAttribute">...</Attribute> <!--
ancestor: AggregationDesignDimension -->
 <!-- or -->
 <Attribute xsi:type="AggregationInstanceAttribute">...</Attribute> <!--
ancestor: AggregationInstanceCubeDimension -->
 <!-- or -->
 <Attribute xsi:type="CubeAttribute">...</Attribute> <!--ancestor:
CubeDimension -->
 <!-- or -->
 <Attribute xsi:type="DimensionAttribute">...</Attribute> <!-- ancestor:
Dimension -->
 <!-- or -->
 <Attribute xsi:type="MeasureGroupAttribute">...</Attribute> <!--
ancestor: RegularMeasureGroupDimension -->
 <!-- or -->
 <Attribute xsi:type="PerspectiveAttribute">...</Attribute> <!-- ancestor:
PerspectiveDimension -->
 <!-- or -->
<Attribute>
 <AttributeID>...</AttributeID>
</Attribute> <!-- ancestor: RelationshipEnd -->
</Attributes>
```

## Element Characteristics

# DataSourceView Element (ASSL)

Article • 10/31/2023

Defines a data source view used by a Analysis Services [Database](#) element.

## Syntax

XML

```
<DataSourceViews>
 <DataSourceView>
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <Description>...</Description>
 <Annotations>...</Annotations>
 <DataSourceID> </DataSourceID>
 <Schema>...</Schema>
 </DataSourceView>
</DataSourceViews>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DataSourceViews</a>

Relationship	Element
Child elements	<a href="#">Annotations</a> , <a href="#">CreatedTimestamp</a> , <a href="#">DataSourceID</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">Name</a> , <a href="#">Schema</a>

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [DataSourceView](#).

# Dimension Element (ASSL)

Article • 10/31/2023

Defines a dimension.

## Syntax

XML

```
<Dimensions>
 <Dimension xsi:type="Dimension">...</Dimension> <!-- ancestor: Database --
->
 <!-- or -->
 <Dimension xsi:type="AggregationDimension">...</Dimension> <!-- ancestor:
Aggregation -->
 <!-- or -->
 <Dimension xsi:type="AggregationDesignDimension">...</Dimension> <!--
ancestor: AggregationDesign -->
 <!-- or -->
 <Dimension xsi:type="AggregationInstanceCubeDimension">...</Dimension>
<!-- ancestor: AggregationInstance -->
 <!-- or -->
 <Dimension xsi:type="CubeDimension">...</Dimension> <!-- ancestor: Cube --
->
 <!-- or -->
 <Dimension xsi:type="MeasureGroupDimension">...</Dimension> <!--
ancestor: MeasureGroup -->
 <!-- or -->
 <Dimension xsi:type="PerspectiveDimension">...</Dimension> <!-- ancestor:
Perspective -->
</Dimensions>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

# DimensionPermission Element (ASSL)

Article • 10/31/2023

Defines the permissions that belong to a particular [Role](#) element for a specific database dimension or cube dimension.

## Syntax

XML

```
<DimensionPermissions>
 <DimensionPermission xsi:type="DimensionPermission">...
</DimensionPermission> <!-- ancestor: Dimension -->
 <!-- or -->
 <DimensionPermission xsi:type="CubeDimensionPermission">...
</DimensionPermission> <!-- ancestor: CubePermission -->
</DimensionPermissions>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	The following are valid Parent (or Ancestor): Data Type pairs:  <a href="#">Dimension:DimensionPermission</a>  <a href="#">CubePermission:</a> <a href="#">CubeDimensionPermission</a>
Default value	None
Cardinality	0-n: Optional element that can occur once or more than once.

## Element Relationships

# ErrorConfiguration Element (ASSL)

Article • 10/31/2023

Specifies settings for handling errors that can occur when the parent element is processed.

## Syntax

XML

```
<Cube> <!-- or Dimension, MeasureGroup, MiningStructure, Partition -->
...
<ErrorConfiguration>
 <KeyErrorLimit>...</KeyErrorLimit>
 <KeyErrorLogFile>...</KeyErrorLogFile>
 <KeyErrorAction>...</KeyErrorAction>
 <KeyErrorLimitAction>...</KeyErrorLimitAction>
 <KeyNotFound>...</KeyNotFound>
 <KeyDuplicate>...</KeyDuplicate>
 <NullKeyConvertedToUnknown>...</NullKeyConvertedToUnknown>
 <NullKeyNotAllowed>...<NullKeyNotAllowed>
</ErrorConfiguration>
...
</Cube >
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

# ForeignKeyColumn Element (ASSL)

Article • 10/31/2023

Identifies the join to a parent table for a relational data source.

## Syntax

XML

```
<ForeignKeyColumns>
 <ForeignKeyColumn xsi:type="DataItem">...</ForeignKeyColumn>
</ForeignKeyColumns>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">DataItem</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">ForeignKeyColumns</a>
Child elements	None

## Remarks

For additional information about the **DataItem** type, including a table of Analysis Services Scripting Language (ASSL) objects and properties of the **DataItem** type, see

[Dataitem Data Type \(ASSL\)](#).

The element that corresponds to the parent of the **ForeignKeyColumns** collection in the Analysis Management Objects (AMO) object model is [TableMiningStructureColumn](#).

# Group Element (ASSL)

Article • 10/31/2023

Defines a group of members bound to an attribute.

## Syntax

XML

```
<Groups>
 <Group>
 <Name>...</Name>
 <Members>...</Members>
 </Group>
<Groups/>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	1-n: Required element that can occur more than once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Groups</a>

# Kpi Element (ASSL)

Article • 10/31/2023

Defines a key performance indicator (KPI) within a [Cube](#) element or a [Perspective](#) element.

## Syntax

XML

```
<Kpis>
 <Kpi> <!-- ancestor: Cube -->
 <Name>...</Name>
 <ID>...</ID>
 <Description>...</Description>
 <Translations>...</Translations>
 <DisplayFolder>...</DisplayFolder>
 <AssociatedMeasureGroupID>...</AssociatedMeasureGroupID>
 <Value>...</Value>
 <Goal>...</Goal>
 <Status>...</Status>
 <Trend>...</Trend>
 <TrendGraphic>...</TrendGraphic>
 <StatusGraphic>...</StatusGraphic>
 <CurrentTimeMember>...</CurrentTimeMember>
 <Annotations>...</Annotations>
 </Kpi>
 <!-- or -->
 <Kpi xsi:type="PerspectiveKpi">...</Kpi> <!-- ancestor: Perspective -->
 </Kpi>
</Kpis>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

[\[+\] Expand table](#)

Ancestor or Parent	Data Type
Cube	None
Perspective	PerspectiveKpi

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	Kpis

# MdxScript Element (ASSL)

Article • 10/31/2023

Contains information about a Multidimensional Expressions (MDX) script that is associated with a [Cube](#) element.

## Syntax

```
XML

<MdxScripts>
 <MdxScript>
 <Name>...</Name>
 <ID>...</ID>
 <Description>...</Description>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <Annotations>...</Annotations>
 <Commands>...</Commands>
 <DefaultScript>...</DefaultScript>
 <CalculationProperties>...</CalculationProperties>
 </MdxScript>
</MdxScripts>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">MdxScripts</a>
Child elements	<a href="#">Annotations</a> , <a href="#">CalculationProperties</a> , <a href="#">Commands</a> , <a href="#">CreatedTimestamp</a> , <a href="#">DefaultScript</a> , <a href="#">Description</a> , <a href="#">ID</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">Name</a>

## Remarks

A script's **DefaultScript** element is set to **True** by default. Setting **DefaultScript** to **True** for a particular script sets **DefaultScript** to **False** for all other scripts.

The corresponding element in the Analysis Management Objects (AMO) object model is [MdxScript](#).

## See Also

## Feedback

Was this page helpful?

 Yes     No

# Measure Element (ASSL)

Article • 10/31/2023

Defines a measure.

## Syntax

XML

```
<Measures>
 <Measure> <!-- ancestor: MeasureGroup -->
 <Name>...</Name>
 <ID>...</ID>
 <Description>...</Description>
 <AggregateFunction>...</AggregateFunction>
 <DataType>...</DataType>
 <Source>...</Source>
 <Visible>...</Visible>
 <MeasureExpression>...</MeasureExpression>
 <DisplayFolder>...</DisplayFolder>
 <FormatString>...</FormatString>
 <BackColor>...</BackColor>
 <ForeColor>...</ForeColor>
 <FontName>...</FontName>
 <FontSize>...</FontSize>
 <FontFlags>...</FontFlags>
 <Translations>...</Translations>
 <Annotations>...</Annotations>
 </Measure>
 <!-- or -->
 <Measure xsi:type="AggregationInstanceMeasure">...</Measure> <!-- parent:
AggregationInstance -->
 <!-- or -->
 <Measure xsi:type="MeasureBinding">...</Measure> <!-- ancestor:
MeasureGroupBinding (out-of-line) -->
 <!-- or -->
 <Measure xsi:type="PerspectiveMeasure">...</Measure> <!-- ancestor:
PerspectiveMeasureGroup -->
</Measures>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

[\[+\] Expand table](#)

Ancestor or Parent	Data Type
AggregationInstance	AggregationInstanceMeasure
MeasureGroup	None
MeasureGroupBinding (out-of-line)	MeasureBinding
PerspectiveMeasureGroup	PerspectiveMeasure

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	Measures
Child elements	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Child elements
MeasureGroup	AggregateFunction, Annotations, BackColor, DataType, Description, DisplayFolder, FontFlags, FontName, FontSize, ForeColor, FormatString, ID, MeasureExpression, Name, Source, Translations, Visible
All others	None

## Remarks

Binding details can be provided for a measure. These details then act as the defaults per partition.

In larger cubes, there may be hundreds of measures and hierarchies. The **DisplayFolder** property defines user appearance on the client. The value of the **DisplayFolder** property can contain any one of the following options:

- Be empty, denoting that the measure does not belong to a folder.
- Contain a single folder name, denoting that the measure should be rendered as belonging to a folder with the same name.
- Contain multiple folder names separated by a backslash (\), denoting an embedded folder hierarchy.

The **DisplayFolder** property also applies to calculated measures and hierarchies.

The corresponding elements in the Analysis Management Objects (AMO) object model are [Measure](#) and [PerspectiveMeasure](#).

## See Also

[Objects \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# MeasureGroup Element (ASSL)

Article • 10/31/2023

Defines a set of measures at the same level of granularity.

## Syntax

XML

```
<MeasureGroups>
 <MeasureGroup> <!-- ancestor: Cube -->
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</Create
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <Description>...</Description>
 <LastProcessed>...</LastProcessed>
 <Translations>...</Translations>
 <Type>...</Type>
 <State>...</State>
 <MeasureQualification>...</MeasureQualification>
 <Measures>...</Measures>
 <DataAggregation>...</DataAggregation>
 <Source>...</Source>
 <StorageMode>...</StorageMode>
 <StorageLocation>...</StorageLocation>
 <IgnoreUnrelatedDimensions>...</IgnoreUnrelatedDimensions>
 <ProactiveCaching>...</ProactiveCaching>
 <EstimatedRows>...</EstimatedRows>
 <ErrorConfiguration>...</ErrorConfiguration>
 <EstimatedSize>...</EstimatedSize>
 <ProcessingMode>...</ProcessingMode>
 <Dimensions>...</Dimensions>
 <Partitions>...</Partitions>
 <AggregationPrefix>...</AggregationPrefix>
 <ProcessingPriority>...</ProcessingPriority>
 <AggregationDesigns>...</AggregationDesigns>
 <Annotations>...</Annotations>
 </MeasureGroup>
 <!-- or -->
 <MeasureGroup xsi:type="MeasureGroupBinding">...</MeasureGroup> <!--
ancestor: CubeBinding -->
 <!-- or -->
 <MeasureGroup xsi:type="PerspectiveMeasureGroup">...</MeasureGroup> <!--
ancestor: Perspective -->
</MeasureGroups>
```

# Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

[\[+\] Expand table](#)

Ancestor or Parent	Data Type
Cube	None
CubeBinding	MeasureGroupBinding
Perspective	PerspectiveMeasureGroup

# Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	MeasureGroups
Child elements	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Child elements
Cube	AggregationDesigns, AggregationPrefix, Annotations, CreatedTimestamp, DataAggregation, Description, Dimensions, ErrorConfiguration, EstimatedRows, EstimatedSize, ID, IgnoreUnrelatedDimensions, LastProcessed, LastSchemaUpdate, MeasureQualification, Measures, Name, Partitions, ProactiveCaching, ProcessingMode, ProcessingPriority, Source, State, StorageLocation, StorageMode, Translations, Type
CubeBinding	None

Ancestor or Parent	Child elements
Perspective	None

## Remarks

All the measures of a measure group must be sourced from a single table. A measure group can define default bindings that can be overridden for each partition.

The **MeasureGroup** element defines details common to measure groups on regular cubes and virtual cubes. Separate subtypes define the details specific to each type.

The **State** property of a **MeasureGroup** has the following values:

- *FullyProcessed* if all partitions are processed.
- *PartiallyProcessed* if at least one partition is processed.
- *Unprocessed* if no partitions are processed.

The corresponding elements in the Analysis Management Objects (AMO) object model are **MeasureGroup** and **PerspectiveMeasureGroup**.

# MiningModelPermission Element (ASSL)

Article • 10/31/2023

Defines the permissions members of a [Role](#) element have on an individual [MiningModel](#) element.

## Syntax

XML

```
<MiningModelPermissions>
 <MiningModelPermission xsi:type="Permission">
 <!-- The following elements extend Permission -->
 <AllowDrillThrough>...</AllowDrillThrough>
 <AllowBrowsing>...</AllowBrowsing>
 </MiningModelPermission>
</MiningModelPermissions>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	<a href="#">Permission</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">MiningModelPermissions</a>
Child elements	<a href="#">AllowBrowsing</a> , <a href="#">AllowDrillThrough</a>

# Remarks

You can enable drillthrough on mining structures by adding the **AllowDrillthrough** permission to the [MiningStructurePermissions](#) collection. If **AllowDrillthrough** is enabled on both the mining structure and the mining model, any member of a role that has [AllowDrillThrough Element \(ASSL\)](#) permissions on the model can query the data mining model, and return structure columns that were not included in the model, by using the following syntax:

SQL

```
SELECT StructureColumn('<column name>') FROM <model>.CASES
```

Therefore, to protect sensitive data or personal information, you should grant **AllowDrillthrough** permission on a mining model only when necessary. For more information, see [AllowDrillThrough Element \(ASSL\)](#).

The corresponding element in the Analysis Management Objects (AMO) object model is [MiningModelPermission](#).

 No

# MiningStructure Element (ASSL)

Article • 10/31/2023

Defines the structure for a set of mining models.

## Syntax

XML

```
<MiningStructures>
 <MiningStructure>
 <Name>...</Name>
 <ID>...</ID>
 <Description>...</Description>
 <Source>...</Source>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <LastProcessed>...</LastProcessed>
 <Translations>...</Translations>
 <Language>...</Language>
 <Collation>...</Collation>
 <ErrorConfiguration>...</ErrorConfiguration>
 <CacheMode>...</CacheMode>
 <Columns>...</Columns>
 <State>...</State>
 <HoldoutActualSize>...</HoldoutActualSize>
 <HoldoutMaxCases>...</HoldoutMaxCases>
 <HoldoutMaxPercent>...</HoldoutMaxPercent>
 <HoldoutSeed>...</HoldoutSeed>
 <MiningStructurePermissions>...</MiningStructurePermissions>
 <MiningModels>...</MiningModels>
 <Annotations>...</Annotations>
 </MiningStructure>
</MiningStructures>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None

Characteristic	Description
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[Expand table](#)

Relationship	Element
Parent elements	<a href="#">MiningStructures</a>
Child elements	<a href="#">Annotations</a> , <a href="#">CacheMode</a> , <a href="#">Collation</a> , <a href="#">Columns</a> , <a href="#">CreatedTimestamp</a> , <a href="#">Description</a> , <a href="#">ErrorConfiguration</a> , <a href="#">HoldoutActualSize</a> , <a href="#">HoldoutMaxCases</a> , <a href="#">HoldoutMaxPercent</a> , <a href="#">HoldoutSeed</a> , <a href="#">ID</a> , <a href="#">Language</a> , <a href="#">LastProcessed</a> , <a href="#">LastSchemaUpdate</a> , <a href="#">MiningModels</a> , <a href="#">MiningStructurePermissions</a> , <a href="#">Name</a> , <a href="#">Source</a> , <a href="#">State</a> , <a href="#">Translations</a>

## Remarks

The mining structure defines the columns and the bindings. After defining a mining structure, you can use that structure to define many mining models. The mining structure, and each mining model it contains, can be processed independently.

### Note

The holdout properties, **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, and **HoldoutActualSize** enable you to define a partition on a mining structure that acts as the test set for all the mining models that are associated with the structure. SQL Server 2005 does not support these properties. Therefore, if you try to use these properties on an instance of SQL Server 2005, Analysis Services will return an error.

# Drillthrough to Structure Columns

In SQL Server 2008, a new permission element has been added to the [MiningStructurePermissions Element \(ASSL\)](#) collection. If you add **AllowDrillthrough** permission to both the [MiningStructurePermissions](#) and [MiningModelPermission](#) collections, drillthrough is enabled from the mining model to the structure, in such a way that members of a role that has **AllowDrillthrough** permissions on the model can query the data mining model, and return structure columns that were not included in the model.

Therefore, to protect sensitive data or personal information, you should construct your data source view to mask sensitive information, and grant **AllowDrillthrough** permission on a mining structure only when necessary. For more information, see [AllowDrillThrough Element \(ASSL\)](#).

The corresponding element in the Analysis Management Objects (AMO) object model is [MiningStructure](#).

---

 Yes

 No

# MiningStructurePermission Element (ASSL)

Article • 10/31/2023

Defines the permissions that members of a [Role](#) element have on an individual [MiningStructure](#) element.

## Syntax

XML

```
<MiningStructurePermissions>
 <MiningStructurePermission xsi:type="Permission">
 <AllowDrillthrough>...</AllowDrillthrough>

 <!-- This element also inherits all the child elements listed in
 Permission -->
 </MiningStructurePermission>
</MiningStructurePermissions>
```

## Element Characteristics

[] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">Permission</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">MiningStructurePermissions</a>

Relationship	Element
Child elements	None

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [MiningStructurePermission](#).

In SQL Server, the permission **AllowDrillthrough** has been extended to apply to a mining structure. When you assign this permission to a role, any user who is a member of that role can directly query the mining structure by using the following syntax:

SQL

```
SELECT <structure column list> FROM <structure>.CASES
```

Moreover, if **AllowDrillthrough** is enabled on both the mining structure and the mining model, users can query structure columns that were not included in the mining model by using the following syntax:

SQL

```
SELECT StructureColumn('<structure column name>' FROM <model>.CASES
```

For example, you create a model using only columns for customer key, customer income, and customer purchases. By using drillthrough, a user can return other structure columns that were not included in the mining model, such as customer contact information.

Therefore, to protect sensitive data or personal information, you should construct your data source view to mask personal information and grant **AllowDrillthrough** permission on a structure only when necessary.

# NameColumn Element (ASSL)

Article • 10/31/2023

Identifies the column that provides the name of the parent element.

## Syntax

XML

```
<DimensionAttribute> <!-- or ScalarMiningStructureColumn -->
...
<NameColumn xsi:type="DataItem">...</NameColumn>
...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	DataItem
Default value	See the table below.
Cardinality	0-1: Optional element that can occur once and only once.

[+] Expand table

Ancestor or Parent	Default Value
DimensionAttribute	Varies (see Remarks)
ScalarMiningStructureColumn	None

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DimensionAttribute</a> , <a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

If the [KeyColumns](#) collection of [DimensionAttribute](#) contains a single [KeyColumn](#) element representing a key column with a string data type, the same [DataItem](#) values are used as default values for the [NameColumn](#) element.

For more information about the [DataItem](#) type, including a table of Analysis Services Scripting Language (ASSL) objects and properties of the [DataItem](#) type, see [DataItem Data Type \(ASSL\)](#).

The elements that correspond to the parents of [NameColumn](#) in the Analysis Management Objects (AMO) object model are [DimensionAttribute](#) and [ScalarMiningStructureColumn](#).

# NamingTemplateTranslation Element (ASSL)

Article • 10/31/2023

Provides a localized translation of the [NamingTemplate](#) element for a parent [DimensionAttribute](#) data type.

## Syntax

XML

```
<NamingTemplateTranslations>
 <NamingTemplateTranslation xsi:type="Translation">...
</NamingTemplateTranslation>
</NamingTemplateTranslations>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">Translation</a>
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">NamingTemplateTranslations</a>
Child elements	None

## Remarks

The value of the **NamingTemplateTranslation** element is used only by parent attributes (in other words, the value of the [Usage](#) element of the **DimensionAttribute** parent is set to *Parent*) to store the localized translation of the **NamingTemplate** value for a given language.

The element that corresponds to the parent of **NamingTemplateTranslations** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# Partition Element (ASSL)

Article • 10/31/2023

Defines a partition of a [MeasureGroup](#) element or a partition binding in an out-of-line [MeasureGroupBinding](#) element.

## Syntax

XML

```
<Partitions>
 <Partition> <!-- ancestor: MeasureGroup -->
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <Description>...</Description>
 <Source>...</Source>
 <ProcessingPriority>...</ProcessingPriority>
 <AggregationPrefix>...</AggregationPrefix>
 <StorageMode>...</StorageMode>
 <ProcessingMode>...</ProcessingMode>
 <ErrorConfiguration>...</ErrorConfiguration>
 <StorageLocation>...</StorageLocation>
 <RemoteDatasourceID>...</RemoteDatasourceID>
 <Slice>...</Slice>
 <ProactiveCaching>...</ProactiveCaching>
 <Type>...</Type>
 <EstimatedSize>...</EstimatedSize>
 <EstimatedRows>...</EstimatedRows>
 <CurrentStorageMode>...</CurrentStorageMode>
 <AggregationDesignID>...</AggregationDesignID>
 <AggregationInstances>...</AggregationInstances>
 <AggregationInstanceSource>...</AggregationInstanceSource>
 <LastProcessed>...</LastProcessed>
 <State>...</State>
 <Annotations>...</Annotations>
 </Partition>
 <!-- or -->
 <Partition xsi:type="PartitionBinding"> <!-- ancestor:
 MeasureGroupBinding -->
 </Partition>
</Partitions>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

[\[+\] Expand table](#)

Ancestor or Parent	Data Type
MeasureGroup	None
MeasureGroupBinding	PartitionBinding

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	Partitions
Child elements	See the table below.

[\[+\] Expand table](#)

Ancestor or Parent	Child elements
MeasureGroup	AggregationDesignID, AggregationInstances, AggregationInstanceSource, AggregationPrefix, Annotations, CreatedTimestamp, CurrentStorageMode, Description, ErrorConfiguration, EstimatedRows, EstimatedSize, ID, LastProcessed, LastSchemaUpdate, Name, ProactiveCaching, ProcessingMode, ProcessingPriority, RemoteDatasourceID, Slice, Source, State, StorageLocation, StorageMode, Type
MeasureGroupBinding	None

## Remarks

This element has the following validations under DeploymentMode value 2 (tabular server mode):

- The following children elements are not supported and should not be used:
  - [ProcessingPriority](#)
  - [AggregationPrefix](#)
  - [StorageLocation](#)
  - [ProcessingMode](#)
  - [ErrorConfiguration](#)
  - [StorageLocation](#)
  - [RemoteDatasourceID](#)
  - [Slice](#)
  - [ProactiveCaching](#)
  - [Type](#)
  - [CurrentStorageMode](#)
  - [AggregationDesignID](#)
  - [AggregationInstances](#)
  - [AggregationInstanceSource](#)

An error might be thrown if any of the above elements is used.

- The [Source](#) element only accepts **Query** binding.

The corresponding element in the Analysis Management Objects (AMO) object model is [Partition](#).

# Perspective Element (ASSL)

Article • 10/31/2023

Defines details for a perspective of a [Cube](#) element.

## Syntax

XML

```
<Perspectives>
 <>Perspective>
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <Description>...</Description>
 <Translations>...</Translations>
 <DefaultMeasure>...</DefaultMeasure>
 <Dimensions>...</Dimensions>
 <MeasureGroups>...</MeasureGroups>
 <Calculations>...</Calculations>
 <Kpis>...</Kpis>
 <Actions>...</Actions>
 <Annotations>...</Annotations>
 </Perspective>
</Perspectives>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	None
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	Perspectives
Child elements	Actions, Annotations, Calculations, CreatedTimestamp, DefaultMeasure, Description, Dimensions, ID, Kpis, LastSchemaUpdate, MeasureGroups, Name, Translations

## Remarks

A perspective provides a subset of a cube, selecting the dimensions, hierarchies, attributes, and other details that are to be included, and defining the slice of data to be included. A perspective is owned by a single cube. It is not possible to override or add objects within a perspective; all dimensions, hierarchies, and other details must exist in the underlying cube. It is not possible to include objects and mark them as not visible.

The corresponding element in the Analysis Management Objects (AMO) object model is [Perspective](#).

# SkippedLevelsColumn Element (ASSL)

Article • 10/31/2023

## ⓘ Note

This feature is discontinued in this version of Microsoft SQL Server. Avoid using this feature in new development work, and plan to modify applications that currently use this feature.

Provides the details of a column that stores the number of skipped (empty) levels between each member and its parent.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <SkippedLevelsColumn xsi:type="DataItem">...</SkippedLevelsColumn>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	DataItem
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The **SkippedLevelsColumn** element is applicable only to parent attributes (in other words, the value of the [Usage](#) element for the **DimensionAttribute** parent is set to *Parent*). The **SkippedLevelsColumn** element contains the column or attribute for the parent attribute that stores the number of skipped levels between each member and its parent member. This allows parent-child hierarchies that are based on the parent attribute to skip levels between members. The values contained in this column or attribute must be nonnegative integers; otherwise, a processing error occurs. If the **SkippedLevelsColumn** element is not specified or contains no value, the current member has a level depth one below its parent member.

For more information about the **DataItem** type, including a table of Analysis Services Scripting Language (ASSL) objects and properties of the **DataItem** table, see [DataItem Data Type \(ASSL\)](#).

The element that corresponds to the parent of **SkippedLevelsColumn** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# Translation Element (ASSL)

Article • 10/31/2023

Provides a localized translation for the parent of the [Translations](#) collection.

## Syntax

XML

```
<Translations>
 <Translation xsi:type="Translation">...</Translation>
 <!-- or -->
 <Translation xsi:type="AttributeTranslation">...</Translation>
</Translations>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">Translation</a> , <a href="#">AttributeTranslation</a>
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Translations</a>
Child elements	None

## Remarks

The corresponding element in the Analysis Management Objects (AMO) object model is [Translation](#).

## See Also

[Objects \(ASSL\)](#)

---

## Feedback

 Yes

 No

# UnaryOperatorColumn Element (ASSL)

Article • 10/31/2023

Defines the details of a column providing a unary operator.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <UnaryOperatorColumn xsi:type="DataItem">...</UnaryOperatorColumn>
 ...
</DimensionAttribute>
```

## Element Characteristics

  [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">DataItem</a>
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

  [Expand table](#)

Relationship	Element
Parent elements	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

For more information about the **DataItem** type, including a table of Analysis Services Scripting Language (ASSL) objects and properties of the **DataItem** type, see [DataItem Data Type \(ASSL\)](#).

The element that corresponds to the parent of **UnaryOperatorColumn** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# UnknownMemberTranslation Element (ASSL)

Article • 10/31/2023

Contains a translation for the caption of the [UnknownMember](#) element for a [Dimension](#) element.

## Syntax

XML

```
<UnknownMemberTranslations>
 <UnknownMemberTranslation xsi:type="Translation">...
 </UnknownMemberTranslation>
</UnknownMemberTranslations>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">Translation</a>
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">UnknownMemberTranslations</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **UnknownMemberTranslation** in the Analysis Management Objects (AMO) object model is [Dimension](#).

# ValueColumn Element (ASSL)

Article • 10/31/2023

Identifies the column that provides the value of the parent element.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <ValueColumn xsi:type="DataItem">...</ValueColumn>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	<a href="#">DataItem</a>
Default value	Varies (see Remarks)
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

If the **NameColumn** element of **DimensionAttribute** is specified, the same **DataItem** values are used as default values for the **ValueColumn** element. If the **NameColumn** element of **DimensionAttribute** is not specified and the **KeyColumns** collection of **DimensionAttribute** contains a single **KeyColumn** element representing a key column with a string data type, the same **DataItem** values are used as default values for the **ValueColumn** element.

For more information about the **DataItem** type, including a table of Analysis Services Scripting Language (ASSL) objects and properties of the **DataItem** type, see [DataItem Data Type \(ASSL\)](#).

The elements that correspond to the parents of **NameColumn** in the Analysis Management Objects (AMO) object model are **DimensionAttribute** and **ScalarMiningStructureColumn**.

# Properties (ASSL)

Article • 12/09/2022

This reference section contains syntax and usage information for each element that acts as an object property in the Analysis Services Scripting Language (ASSL) schema.

Although the ASSL schema contains only XML elements, from a developer's point of view, the elements described in this section correspond to properties that describe objects.

Properties are leaf-level elements in the ASSL schema, and do not have child elements or elements that correspond to properties of their own.

In a few cases, a leaf-level element in the schema that may appear to be a property is classified as an object because the element's type is an object type. For example, the **Source** of a **Dimension** object is of type **DimensionBinding**.

## In This Section

[+] Expand table

Element	Description
<a href="#">Access Element (ASSL)</a>	Indicates the level of access given to a <a href="#">CellPermission</a> element.
<a href="#">Account Element (ImpersonationInfo) (ASSL)</a>	Contains the name of the user account for the <a href="#">ImpersonationInfo</a> data type.
<a href="#">AccountType Element (ASSL)</a>	Contains the name of an account type defined in a <a href="#">Database</a> element.
<a href="#">ActionID Element (ASSL)</a>	Contains the name of an <a href="#">Action</a> element defined on a <a href="#">Cube</a> element which is made available in a <a href="#">Perspective</a> element as a <a href="#">PerspectiveAction</a> element.
<a href="#">Administer Element (ASSL)</a>	Indicates whether the associated permission includes the right to administer a <a href="#">Database</a> element.
<a href="#">AggregateFunction Element (ASSL)</a>	Defines the type of aggregate function used by a <a href="#">Measure</a> element.
<a href="#">AggregationDesignID Element (ASSL)</a>	Identifies the <a href="#">AggregationDesign</a> element associated with the <a href="#">Partition</a> element.

Element	Description
<a href="#">AggregationFunction Element (ASSL)</a>	Contains the aggregation function to use for the account type.
<a href="#">AggregationID Element (ASSL)</a>	Identifies the aggregation definition from the <b>AggregationDesign</b> element used to create the aggregation instance.
<a href="#">AggregationInstanceSource Element (ASSL)</a>	Identifies the source of data for user-defined aggregation instances bound to a <b>Partition</b> element.
<a href="#">AggregationPrefix Element (ASSL)</a>	Defines the common prefix to be used for aggregation names throughout the associated parent element.
<a href="#">AggregationStorage Element (ASSL)</a>	Identifies the storage method for aggregations.
<a href="#">AggregationType Element (ASSL)</a>	Defines the type of aggregation stored by the <b>Partition</b> element.
<a href="#">AggregationUsage Element (ASSL)</a>	Controls how the Aggregation Designer in Analysis Services designs aggregations.
<a href="#">Algorithm Element (ASSL)</a>	Defines the algorithm used by a <b>MiningModel</b> element.
<a href="#">Alias Element (ASSL)</a>	Defines an alias for an <b>Account</b> element.
<a href="#">AllMemberAggregationUsage Element (ASSL)</a>	Controls how the Aggregation Designer in Analysis Services designs aggregations.
<a href="#">AllMemberName Element (ASSL)</a>	Contains the caption in the default language for the All member of a <b>Hierarchy</b> element.
<a href="#">AllowBrowsing Element (ASSL)</a>	Defines whether the members of a <b>Role</b> element have browse permission on a <b>MiningModel</b> element.
<a href="#">AllowDrillThrough Element (ASSL)</a>	Determines whether drillthrough is permitted on the parent element.
<a href="#">AllowDuplicateNames Element (ASSL)</a>	Determines whether duplicate names are allowed in a <b>Hierarchy</b> element.
<a href="#">AllowedSet Element (ASSL)</a>	Contains a set expression that defines the set of allowed permissions for a <b>Role</b> element on an attribute.
<a href="#">Application Element (ASSL)</a>	Identifies the application associated with an <b>Action</b> element.
<a href="#">AssociatedMeasureGroupID Element (ASSL)</a>	Contains the identifier (ID) of the <b>MeasureGroup</b> element associated with a <b>CalculationProperty</b> element or a <b>Kpi</b> element.

Element	Description
<a href="#">AttributeAllMemberName Element (ASSL)</a>	Contains the caption, in the default language, for the All member of the dimension.
<a href="#">AttributeHierarchyDisplayFolder Element (ASSL)</a>	Identifies the folder in which to display the associated attribute hierarchy.
<a href="#">AttributeHierarchyEnabled Element (ASSL)</a>	Determines whether an attribute hierarchy is enabled for the attribute.
<a href="#">AttributeHierarchyOptimizedState Element (ASSL)</a>	Determines the level of optimization applied to the attribute hierarchy.
<a href="#">AttributeHierarchyOrdered Element (ASSL)</a>	Determines whether the associated attribute hierarchy is ordered.
<a href="#">AttributeHierarchyVisible Element (ASSL)</a>	Determines whether the attribute hierarchy is visible to client applications.
<a href="#">AttributID Element (ASSL)</a>	Contains the ID of the attribute associated with the parent element.
<a href="#">Audit Element (ASSL)</a>	Specifies that a <a href="#">Trace</a> element cannot drop any events, even if this results in degraded performance on the server.
<a href="#">AutoRestart Element (ASSL)</a>	Determines whether a <a href="#">Trace</a> element should automatically restart if the Analysis Services service stops and restarts.
<a href="#">BackColor Element (ASSL)</a>	Describes color-related display characteristics of the parent element.
<a href="#">CacheMode Element (ASSL)</a>	Determines the caching mechanism used for training data retrieved while processing a mining structure.
<a href="#">CalculationReference Element (ASSL)</a>	Contains the name of the named set or calculated cell referenced by the <a href="#">CalculationProperty</a> element.
<a href="#">CalculationType Element (ASSL)</a>	Describes the type of calculation defined in the associated <a href="#">CalculationProperty</a> element.
<a href="#">CalendarEndDate Element (ASSL)</a>	Defines the end date of the calendar period for a <a href="#">TimeBinding</a> element.
<a href="#">CalendarLanguage Element (ASSL)</a>	Defines the calendar language used for the <a href="#">TimeBinding</a> element.
<a href="#">CalendarStartDate Element (ASSL)</a>	Defines the start date of the calendar period for the <a href="#">TimeBinding</a> element.
<a href="#">Caption Element (ASSL)</a>	Contains the caption for the associated parent element.

Element	Description
CaptionIsMdx Element (ASSL)	Defines whether the caption for the <b>Action</b> element is a Multidimensional Expressions (MDX) expression.
Cardinality Element (ASSL)	Indicates the cardinality of the relationship described by an <a href="#">AttributeRelationship</a> or <a href="#">RegularMeasureGroupDimension</a> .
CaseCubeDimensionID Element (ASSL)	Contains the ID of the cube dimension that relates the data mining dimension to the measure group.
ClassifiedColumnID Element (ASSL)	Contains the ID of a related column that is classified by the <a href="#">ScalarMiningStructureColumn</a> element.
Collation Element (ASSL)	Determines the collation used by the parent element.
ColumnID Element (ColumnBinding) (ASSL)	Contains the ID of the column within the table to which the data item is bound.
ColumnID Element (EventColumn) (ASSL)	Contains the ID of the column of information to be captured for an event as part of a <a href="#">Trace</a> element.
Condition Element (ASSL)	Contains an MDX expression that determines whether the <b>Action</b> parent element applies to the target.
ConnectionString Element (ASSL)	Contains the encrypted connection string for a <a href="#">DataSource</a> element.
ConnectionStringSecurity Element (ASSL)	Specifies whether the user's password is stripped from the data source connection string for security purposes.
Content Element (ASSL)	Describes the content of the column in the <a href="#">MiningStructure</a> element.
CreatedTimestamp Element (ASSL)	Contains the read-only creation timestamp of the parent element.
CubeDimensionID Element (ASSL)	Identifies the <a href="#">CubeDimension</a> element associated with the parent element.
CubeID Element (ASSL)	Identifies the <a href="#">Cube</a> element associated with a <a href="#">Binding</a> element.
CurrentStorageMode Element (ASSL)	Determines the current storage mode for the parent element.
CurrentTimeMember Element (ASSL)	Defines the current member of a time dimension associated with a <a href="#">Kpi</a> element.
DataAggregation Element (ASSL)	Determines whether the instance can aggregate persisted data or cached data for the <a href="#">MeasureGroup</a> .

Element	Description
<a href="#">DatabaseID Element (ASSL)</a>	Identifies the <b>Database</b> element associated with an out-of-line <b>Binding</b> element.
<a href="#">DataSize Element (ASSL)</a>	Contains the size in bytes of a <b>DataItem</b> element.
<a href="#">DataSourceID Element (ASSL)</a>	Identifies the <b>DataSource</b> element associated with the parent element.
<a href="#">DataSourceImpersonationInfo Element (ASSL)</a>	Contains the information used to determine impersonation behavior when connecting to the data source for a <b>Database</b> element.
<a href="#">DataSourceViewID Element (ASSL)</a>	Identifies the <b>DataSourceView</b> element associated with the <b>Binding</b> parent element.
<a href="#">DataType Element (ASSL)</a>	Defines the data type of the associated element.
<a href="#">DbSchemaName Element (ASSL)</a>	Contains the name of the schema used by the parent element in the table identified by the <b>DbTableName</b> element.
<a href="#">DbTableName Element (ASSL)</a>	Contains the name of the table to which the parent element is bound.
<a href="#">Default Element (ASSL)</a>	Determines whether the <b>DrillThroughAction</b> is the default drillthrough action.
<a href="#">DefaultMeasure Element (ASSL)</a>	Contains an MDX language expression that defines the default measure for a <b>Cube</b> or <b>Perspective</b> element.
<a href="#">DefaultMember Element (ASSL)</a>	Contains an MDX expression that identifies the default member of the parent element.
<a href="#">DefaultScript Element (ASSL)</a>	Identifies the default <b>MdxScript</b> element in the <b>MdxScripts</b> collection.
<a href="#">DefaultValue Element (ASSL)</a>	Contains the read-only default value of the associated <b>ServerProperty</b> element.
<a href="#">DeniedSet Element (ASSL)</a>	Contains a set expression that defines the list of permissions that are denied on the associated attribute.
<a href="#">DependsOnDimensionID Element (ASSL)</a>	Contains the ID of another dimension on which the parent dimension depends.
<a href="#">Description Element (ASSL)</a>	Contains the description of the parent element.
<a href="#">DimensionID Element (ASSL)</a>	Contains the ID of the dimension.
<a href="#">DiscretizationBucketCount Element</a>	Contains the number of buckets into which to discretize.

Element	Description
(ASSL)	
DiscretizationMethod Element (ASSL)	Defines the method to be used for discretization.
DisplayFlag Element (ASSL)	Contains a read-only hint that indicates whether user interface components should display the associated <b>ServerProperty</b> element.
DisplayFolder Element (ASSL)	Specifies the folder in which to list the parent element. Analysis Services applications for developers and administrators may support the use of display folders to categorize multiple elements visually.
Distribution Element (ASSL)	Contains a provider-specific value that describes how scalar values are distributed within a column of a <b>MiningStructure</b> element.
Edition Element (ASSL)	Contains the read-only edition of the instance of Analysis Services represented by the <b>Server</b> element.
Enabled Element (ASSL)	Indicates whether the parent element is enabled.
EndOfData Element (ASSL)	Indicates the end of data received from a <b>PushedDataSource</b> element.
EstimatedCount Element (ASSL)	Contains the estimated number of members for an attribute.
EstimatedPerformanceGain Element (ASSL)	Contains the read-only percentage of estimated performance gain for the partition.
EstimatedRows Element (ASSL)	Contains the estimated number of rows represented by the parent element.
EstimatedSize Element (ASSL)	Contains the read-only estimated size, in bytes, of the parent element.
EventID Element (ASSL)	Uniquely identifies an <b>Event</b> element that is to be captured as part of a <b>Trace</b> element.
Expression Element (ASSL)	Contains an MDX expression that defines the contents of the parent element.
Filter Element (Binding) (ASSL)	Contains an MDX expression that filters the contents of the parent element.
Filter Element (Trace) (ASSL)	Contains an XML document fragment that describes the <b>Trace</b> filter.

Element	Description
<a href="#">FirstDayOfWeek Element (ASSL)</a>	Defines the first day of the week for a <b>TimeBinding</b> element.
<a href="#">FiscalFirstDayOfMonth Element (ASSL)</a>	Defines the first day of the fiscal month for a <b>TimeBinding</b> element.
<a href="#">FiscalFirstMonth Element (ASSL)</a>	Defines the first month of the fiscal period for a <b>TimeBinding</b> element.
<a href="#">FiscalYearName Element (ASSL)</a>	Defines the naming convention for the name of the fiscal year for a <b>TimeBinding</b> element.
<a href="#">FontFlags Element (ASSL)</a>	Describes font-related display characteristics of the <b>CalculationProperty</b> or <b>Measure</b> parent element.
<a href="#">FontName Element (ASSL)</a>	Describes font-related display characteristics of the <b>CalculationProperty</b> or <b>Measure</b> parent element.
<a href="#">FontSize Element (ASSL)</a>	Describes font-related display characteristics of the <b>CalculationProperty</b> or <b>Measure</b> parent element.
<a href="#">ForceRebuildInterval Element (ASSL)</a>	Determines the amount of time, starting when a fresh multidimensional OLAP (MOLAP) image becomes available, after which MOLAP imaging unconditionally starts.
<a href="#">ForeColor Element (ASSL)</a>	Describes color-related display characteristics of the <b>CalculationProperty</b> or <b>Measure</b> parent element.
<a href="#">Format Element (ASSL)</a>	Contains the required format of the <b>DataItem</b> element.
<a href="#">FormatString Element (ASSL)</a>	Describes the display format for a <b>CalculationProperty</b> element or a <b>Measure</b> element.
<a href="#">Goal Element (ASSL)</a>	Identifies the desired goal in a <b>Kpi</b> element.
<a href="#">GranularityAttributeID Element (ASSL)</a>	Contains the ID of the attribute associated with the parent <b>MeasureGroupAttributeBinding</b> data type.
<a href="#">HideMemberIf Element (ASSL)</a>	Indicates whether and when a member in a level should be hidden from client applications.
<a href="#">HierarchyID Element (ASSL)</a>	Contains the ID for a <b>CubeHierarchy</b> , <b>MeasureGroupHierarchy</b> , or <b>PerspectiveHierarchy</b> element.
<a href="#">HierarchyUniqueNameStyle Element (ASSL)</a>	Determines how unique names are generated for hierarchies that are contained within the <b>CubeDimension</b> .
<a href="#">ID Element (ASSL)</a>	Contains the unique ID of the parent element.

Element	Description
<a href="#">IgnoreUnrelatedDimensions Element (ASSL)</a>	Determines whether unrelated dimensions are forced to their top level when members of dimensions that are unrelated to the measure group are included in a query.
<a href="#">ImpersonationInfo Element (ASSL)</a>	Contains the information that is used to determine impersonation behavior when accessing or executing an assembly.
<a href="#">ImpersonationInfoSecurity Element (ASSL)</a>	Contains a read-only value that indicates if any changes were made to the security credentials that are supplied in the <b>ImpersonationInfo</b> data type.
<a href="#">ImpersonationMode Element (ASSL)</a>	Contains a value that indicates the method of impersonation for elements that are derived from the <b>ImpersonationInfo</b> data type.
<a href="#">InstanceSelection Element (ASSL)</a>	Provides a hint to client applications to suggest how a list of items should be displayed, based on the expected number of items in the list.
<a href="#">IntermediateCubeDimensionID Element (ASSL)</a>	Contains the ID of the dimension that relates a reference dimension to a measure group.
<a href="#">IntermediateGranularityAttributeID Element (ASSL)</a>	Contains the ID of the granularity attribute in the intermediate cube dimension that is used to relate a reference dimension to an intermediate dimension.
<a href="#">InvalidXmlCharacters Element (ASSL)</a>	Specifies the handling method for XML characters in the source data that are not valid.
<a href="#">Invocation Element (ASSL)</a>	Specifies how an <b>Action</b> should be invoked.
<a href="#">IsAggregatable Element (ASSL)</a>	Specifies whether the values of the <b>DimensionAttribute</b> element can be aggregated.
<a href="#">IsKey Element (ASSL)</a>	Indicates whether the column provides the key for the case in a <b>MiningStructure</b> element.
<a href="#">Isolation Element (ASSL)</a>	Indicates the isolation level for an element that is derived from the <b>DataSource</b> data type.
<a href="#">KeyDuplicate Element (ASSL)</a>	Determines how Analysis Services handles a duplicate key error if it encounters one during processing.
<a href="#">KeyErrorAction Element (ASSL)</a>	Specifies the action for Analysis Services to take when an error occurs on a key.
<a href="#">KeyErrorLimit Element (ASSL)</a>	Contains the number of acceptable errors during processing.

Element	Description
<a href="#">KeyErrorLimitAction Element (ASSL)</a>	Specifies the action that Analysis Services takes when the key error count that is specified in the <a href="#">KeyErrorLimit</a> element is reached.
<a href="#">KeyErrorLogFile Element (ASSL)</a>	Contains the file name for logging processing errors.
<a href="#">KeyNotFound Element (ASSL)</a>	Specifies how Analysis Services responds when it encounters a referential integrity error.
<a href="#">KeyUniquenessGuarantee Element (ASSL)</a>	Indicates whether the relationship between the attribute key and its name, and the relationship to related attributes, is guaranteed to be valid.
<a href="#">KpiID Element (ASSL)</a>	Contains an ID that associates a <a href="#">Kpi</a> element with a <a href="#">Perspective</a> element.
<a href="#">Language Element (ASSL)</a>	Contains the language identifier of the parent element.
<a href="#">LastProcessed Element (ASSL)</a>	Contains the read-only timestamp that indicates when the database that contains the parent element was last processed.
<a href="#">LastSchemaUpdate Element (ASSL)</a>	Contains the read-only metadata update timestamp of the parent element.
<a href="#">LastUpdate Element (ASSL)</a>	Contains a read-only timestamp that indicates the last time that the associated <a href="#">Database</a> or any of the major objects that the database contains were altered.
<a href="#">Latency Element (ASSL)</a>	Defines the "grace period" between the earliest notification and the moment when the MOLAP images are destroyed.
<a href="#">LogFileAppend Element (ASSL)</a>	Determines whether the <a href="#">Trace</a> element appends its logging output to the existing log file, or overwrites it.
<a href="#">LogFileAppend Element (ASSL)</a>	Contains the file name of the log file for the <a href="#">Trace</a> element.
<a href="#">LogFileRollover Element (ASSL)</a>	Specifies whether logging of <a href="#">Trace</a> output should roll over to a new file or should stop when the maximum log file size that is specified in <a href="#">LogFileSize</a> is reached.
<a href="#">LogFileSize Element (ASSL)</a>	Specifies the maximum log file size, in megabytes.
<a href="#">ManagedProvider Element (ASSL)</a>	Contains the name of the managed provider that is used by an element that is derived from the <a href="#">DataSource</a> data type.

Element	Description
<a href="#">ManufacturingExtraMonthQuarter Element (ASSL)</a>	Defines the month of the manufacturing period to which an extra month is assigned for a <b>TimeBinding</b> element.
<a href="#">ManufacturingFirstMonth Element (ASSL)</a>	Defines the first manufacturing month for a <b>TimeBinding</b> element.
<a href="#">ManufacturingFirstWeekOfMonth Element (ASSL)</a>	Defines the first week of the manufacturing month for a <b>TimeBinding</b> element.
<a href="#">MasterDataSourceID Element (ASSL)</a>	Contains the master data source ID for a <b>Database</b> element.
<a href="#">Materialization Element (ASSL)</a>	Indicates the type of relationship between the measure group and the reference dimension.
<a href="#">MaxActiveConnections Element (ASSL)</a>	Contains the maximum number of concurrent connections allowed by an element that is derived from the <b>DataSource</b> data type.
<a href="#">MdxMissingMemberMode Element (ASSL)</a>	Determines how missing members are handled for MDX statements.
<a href="#">MeasureExpression Element (ASSL)</a>	Contains the MDX expression that defines a measure.
<a href="#">MeasureGroupID Element (ASSL)</a>	Associates a <b>MeasureGroup</b> with the parent element, binding, or out-of-line binding.
<a href="#">MeasureID Element (ASSL)</a>	Associates a <b>Measure</b> element with the parent element.
<a href="#">MeasureQualificaton Element (ASSL)</a>	Determines whether a prefix is applied to measures in the <b>MeasureGroup</b> .
<a href="#">MemberNamesUnique Element (ASSL)</a>	Determines whether member names under the parent element must be unique.
<a href="#">MemberUniqueNameStyle Element (ASSL)</a>	Determines how unique names are generated for members of hierarchies contained within the <b>CubeDimension</b> element.
<a href="#">MembersWithData Element (ASSL)</a>	Determines whether to display data members for non-leaf members in the parent attribute.
<a href="#">MembersWithDataCaption Element (ASSL)</a>	Provides a template string that is used to create captions for system-generated data members.
<a href="#">MimeType Element (ASSL)</a>	Contains the Multipurpose Internet Mail Extensions (MIME) type, if applicable, of the data represented by the parent <b>DataItem</b> element.
<a href="#">MiningModelID Element (ASSL)</a>	Associates a mining model with a data mining dimension.

Element	Description
<a href="#">Name Element (ASSL)</a>	Contains the name of the parent element.
<a href="#">NamingTemplate Element (ASSL)</a>	Defines how levels are named in a parent-child hierarchy constructed from the <b>DimensionAttribute</b> parent element.
<a href="#">NonEmptyBehavior Element (ASSL)</a>	Determines the non-empty behavior associated with the parent of the <b>CalculationProperty</b> element.
<a href="#">NotificationTechnique Element (ASSL)</a>	Specifies whether or an external client application processes the notifications.
<a href="#">NullKeyConvertedToUnknown Element (ASSL)</a>	Specifies the action to be taken when a null conversion error is encountered.
<a href="#">NullKeyNotAllowed Element (ASSL)</a>	Determines how the Analysis Services processing engine handles a null key error encountered during processing.
<a href="#">NullProcessing Element (ASSL)</a>	Defines how null values are processed.
<a href="#">OnlineMode Element (ASSL)</a>	Specifies whether the database is brought back online immediately when the rebuilding of the cache is initiated, or only when the rebuilding of the cache is complete.
<a href="#">OptimizedState Element (ASSL)</a>	Determines the level of optimization that is applied to the hierarchy.
<a href="#">Optionality Element (ASSL)</a>	Indicates the optionality of the members for an <b>AttributeRelationship</b> element.
<a href="#">OrderBy Element (ASSL)</a>	Describes how to order the members contained in the attribute.
<a href="#">OrderByAttributeID Element (ASSL)</a>	Identifies another attribute by which to order the members of the <b>Dimension</b> attribute.
<a href="#">Ordinal Element (ASSL)</a>	Indicates the ordinal number to bind to in collections such as keys and translations.
<a href="#">OverrideBehavior Element (ASSL)</a>	Indicates the override behavior of the relationship described by an <b>AttributeRelationship</b> element.
<a href="#">PartitionID Element (ASSL)</a>	Associates a <b>Partition</b> element with a parent element, binding, or out-of-line binding.
<a href="#">Password Element (ASSL)</a>	Contains the password of the user account for the <b>ImpersonationInfo</b> element.
<a href="#">Path Element (ASSL)</a>	Contains the path, as provided by an instance of Reporting Services, of a report used by the <b>ReportAction</b> element.

Element	Description
<a href="#">PendingValue Element (ASSL)</a>	Contains the read-only pending value of the associated <a href="#">ServerProperty</a> element.
<a href="#">PermissionSet Element (ASSL)</a>	Identifies the permission set associated with a .NET Framework assembly.
<a href="#">Persistence Element (ASSL)</a>	Determines which parts of the bound source data are dynamic and are checked for updates using the frequency specified by the <a href="#">RefreshPolicy</a> element.
<a href="#">Process Element (ASSL)</a>	Determines whether a user can process the owner of the parent element.
<a href="#">ProcessingMode Element (ASSL)</a>	Indicates whether the instance should index and aggregate during or after processing.
<a href="#">ProcessingPriority Element (ASSL)</a>	Determines the processing priority of the parent object during background operations, for example lazy aggregation, indexing, or clustering.
<a href="#">ProcessingQuery Element (ASSL)</a>	Contains the parameterized text of the query to execute for notification of incremental processing status.
<a href="#">ProductName Element (ASSL)</a>	Contains the read-only product name of the instance of Analysis Services that is associated with a <a href="#">Server</a> element.
<a href="#">Query Element (ASSL)</a>	Contains the text of the query to execute for the notification.
<a href="#">QueryDefinition Element (ASSL)</a>	Contains an opaque expression for a query associated with a <a href="#">DataSource</a> element in a <a href="#">QueryBinding</a> element.
<a href="#">Read Element (ASSL)</a>	Determines whether data or metadata can be read for a given <a href="#">CubeDimensionPermission</a> or <a href="#">Permission</a> element.
<a href="#">ReadDefinition Element (ASSL)</a>	Determines whether members can read the definition of the database or the definition of objects in the database.
<a href="#">ReadSourceData Element (ASSL)</a>	Determines how unique names are generated for hierarchies that are contained within the <a href="#">CubePermission</a> .
<a href="#">RefreshInterval Element (ASSL)</a>	Specifies the interval at which the bound data associated with the parent element is refreshed.
<a href="#">RefreshPolicy Element (ASSL)</a>	Determines how often the dynamic part of the dimension or measure group (as specified by the <a href="#">Persistence</a> element) is checked for changes.

Element	Description
<a href="#">RelationshipType Element (ASSL)</a>	Indicates whether member relationships for an <b>AttributeRelationship</b> can be changed.
<a href="#">RemoteDatasourceID Element (ASSL)</a>	Specifies the ID of the OLAP data source that points to the instance of Analysis Services that stores the remote partition.
<a href="#">ReportingFirstMonth Element (ASSL)</a>	Defines the first reporting month for the <b>TimeBinding</b> element.
<a href="#">ReportingFirstWeekOfMonth Element (ASSL)</a>	Defines the first week of the reporting month for the <b>TimeBinding</b> element.
<a href="#">ReportingWeekToMonthPattern Element (ASSL)</a>	Defines the reporting week-to-month pattern for the <b>TimeBinding</b> element.
<a href="#">ReportServer Element (ASSL)</a>	Contains the name of the Reporting Services instance that is used by the <b>ReportAction</b> .
<a href="#">RequiresRestart Element (ASSL)</a>	Contains a read-only value associated with a <b>ServerProperty</b> element that determines whether changing the value of the server property requires that the instance be restarted for the change to take effect.
<a href="#">RoleID Element (ASSL)</a>	Identifies the role for which permissions are being defined.
<a href="#">Root Element (ASSL)</a>	Contains the data (rowset) for a data source.
<a href="#">RootMemberId Element (ASSL)</a>	Determines how the root member or members of a parent attribute are identified.
<a href="#">Schema Element (ASSL)</a>	Contains the schema of the data source view.
<a href="#">ScriptCacheProcessingMode Element (ASSL)</a>	Indicates whether the server should build the script cache during processing or after processing.
<a href="#">SilenceInterval Element (ASSL)</a>	Defines the minimum amount of time the instance of Analysis Services pauses before starting the MOLAP imaging process.
<a href="#">SilenceOverrideInterval Element (ASSL)</a>	Defines the amount of time that must elapse after receiving initial notification before MOLAP imaging begins unconditionally.
<a href="#">Slice Element (ASSL)</a>	Contains an MDX expression defining the slice contained in a partition.
<a href="#">SolveOrder Element (ASSL)</a>	Indicates the solve order in which the <b>CalculationProperty</b> element is applied to a calculated member or calculated

Element	Description
	cell definition.
<a href="#">Source Element (Binding) (ASSL)</a>	Identifies the source of data to which the parent element is bound.
<a href="#">Source Element (ComAssembly) (ASSL)</a>	Contains the file name or programmatic identifier (ProgID) for a Component Object Model (COM) component.
<a href="#">Source Element (Measure) (ASSL)</a>	Contains the details of the source containing the value of the <b>Measure</b> element.
<a href="#">SourceAttributeID Element (ASSL)</a>	Contains the ID of the source attribute on which the <a href="#">Level</a> element is based.
<a href="#">SourceColumnID Element (ASSL)</a>	Contains the ID of the source mining structure column in the ancestor <b>MiningStructure</b> element.
<a href="#">State Element (ASSL)</a>	Contains a read-only value that describes the current processing state of the parent element.
<a href="#">Status Element (ASSL)</a>	Contains an MDX expression that returns a status indicator for a <b>Kpi</b> element.
<a href="#">StatusGraphic Element (ASSL)</a>	Contains the recommended graphical representation of the status of the <b>Kpi</b> element.
<a href="#">StopTime Element (ASSL)</a>	Specifies the date and time at which a <b>Trace</b> element should stop.
<a href="#">StorageLocation Element (ASSL)</a>	Contains the file system storage location for the contents of the parent element.
<a href="#">StorageMode Element (ASSL)</a>	Determines the storage mode for the parent element.
<a href="#">TableID Element (ASSL)</a>	Contains the ID of the table (from the <b>DataSourceView</b> element) associated with the parent element.
<a href="#">Target Element (ASSL)</a>	Identifies the target of the <b>Action</b> element.
<a href="#">TargetType Element (ASSL)</a>	Identifies the item type of the item identified in the <b>Target</b> element.
<a href="#">Text Element (ASSL)</a>	Contains the text of a <b>Command</b> element.
<a href="#">Timeout Element (ASSL)</a>	Specifies the time, in seconds, after which an attempt to retrieve data reports a timeout.
<a href="#">Trend Element (ASSL)</a>	Contains an MDX expression that returns a trend indicator for a <b>Kpi</b> element.

Element	Description
<a href="#">TrendGraphic Element (ASSL)</a>	Contains the recommended graphical representation of the trend of the <b>Kpi</b> element.
<a href="#">Trimming Element (ASSL)</a>	Specifies how data from the data source is trimmed.
<a href="#">Type Element (Action) (ASSL)</a>	Contains the type of the <b>Action</b> element.
<a href="#">Type Element (Binding) (ASSL)</a>	Contains the type of the attribute binding.
<a href="#">Type Element (ClrAssemblyFile) (ASSL)</a>	Specifies the file type of one of the files that belong to a .NET Framework assembly.
<a href="#">Type Element (Dimension) (ASSL)</a>	Provides information about the contents of the dimension.
<a href="#">Type Element (DimensionAttribute) (ASSL)</a>	Contains the type of the attribute.
<a href="#">Type Element (MeasureGroup) (ASSL)</a>	Specifies the type of the <b>MeasureGroup</b> .
<a href="#">Type Element (MeasureGroupAttribute) (ASSL)</a>	Contains the type of a <b>MeasureGroupAttribute</b> element.
<a href="#">Type Element (MiningStructureColumn) (ASSL)</a>	Contains the type of the <b>MiningStructureColumn</b> element.
<a href="#">Type Element (Partition) (ASSL)</a>	Contains the type of the <b>Partition</b> element.
<a href="#">Type Element (PerspectiveCalculation) (ASSL)</a>	Indicates the type of the <b>PerspectiveCalculation</b> element.
<a href="#">UnknownMember Element (ASSL)</a>	Indicates whether the unknown member is visible.
<a href="#">UnknownMemberName Element (ASSL)</a>	Contains the caption, in the default language of the dimension, for the unknown member of the dimension.
<a href="#">Usage Element (DimensionAttribute) (ASSL)</a>	Describes how an attribute is used.
<a href="#">Usage Element (MiningModelColumn) (ASSL)</a>	Describes how the associated column in the parent <b>MiningStructure</b> is used.
<a href="#">Value Element (ASSL)</a>	Contains the value of the parent element.
<a href="#">Version Element (ASSL)</a>	Contains the read-only version number of the instance of Analysis Services represented by the <b>Server</b> element.
<a href="#">Visibility Element (ASSL)</a>	Defines the visibility of an <b>Annotation</b> element.

Element	Description
<a href="#">Visible Element (ASSL)</a>	Determines the visibility of the parent element.
<a href="#">VisualTotals Element (ASSL)</a>	Contains an MDX expression that determines whether visual totals are displayed for members of this attribute.
<a href="#">Write Element (ASSL)</a>	Determines whether data or metadata can be written for a given <b>CubeDimensionPermission</b> or <b>Permission</b> element.
<a href="#">WriteEnabled Element (ASSL)</a>	Indicates whether dimension writebacks are available (subject to security permissions).

# Access Element (ASSL)

Article • 10/31/2023

Indicates the level of access given to a [CellPermission](#) element.

## Syntax

XML

```
<CellPermission>
 ...
 <Access>...</Access>
 ...
</CellPermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CellPermission</a>
Child elements	None

## Remarks

The value for this element is limited to one of the strings listed in the following table.

Value	Description
<i>Read</i>	Read-only access is allowed.
<i>ReadContingent</i>	Read-contingent access is allowed.
<i>ReadWrite</i>	Read-write access is allowed.

The enumeration that corresponds to the allowed values for **Access** in the Analysis Management Objects (AMO) object model is [CellPermissionAccess](#).

# Account Element (ImpersonationInfo) (ASSL)

Article • 10/31/2023

Contains the name of the user account for the [ImpersonationInfo](#) data type.

## Syntax

XML

```
<ImpersonationInfo
...
<Account>...</Account>
...
</Action>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">ImpersonationInfo</a>
Child elements	None

## Remarks

The value of the **Account** element, as well as the value of the **Password** element, is used for impersonation purposes if the value of the **ImpersonationMode** element for any element derived from the **ImpersonationInfo** data type is set to *ImpersonateAccount*.

# AccountType Element (ASSL)

Article • 10/31/2023

Contains the name of an account type defined in a [Database](#) element.

## Syntax

XML

```
<Account>
 ...
 <AccountType>...</AccountType>
 ...
</Account>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Account</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

Value	Description
<i>Income</i>	The account is an income account.
<i>Expense</i>	The account is an expense account.
<i>Flow</i>	The account is a cash flow account.
<i>Balance</i>	The account is a balance account.
<i>Asset</i>	The account is an asset account.
<i>Liability</i>	The account is a liability account.
<i>Statistical</i>	The account is a statistical account.

The enumeration corresponding to the allowed values for **AccountType** in the Analysis Management Objects (AMO) object model is [AccountTypes](#).

# ActionID Element (ASSL)

Article • 10/31/2023

Contains the name of an [Action](#) element defined on a [Cube](#) element that is made available in a [Perspective](#) element as a [PerspectiveAction](#) element.

## Syntax

XML

```
<PerspectiveAction>
 <ActionID>...</ActionID>
</PerspectiveAction>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">PerspectiveAction</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **ActionID** in the Analysis Management Objects (AMO) object model is [PerspectiveAction](#).

# Administer Element (ASSL)

Article • 10/31/2023

Indicates whether the associated permission includes the right to administer a [Database](#) element.

## Syntax

XML

```
<DatabasePermission>
 ...
 <Administer>...</Administer>
 ...
</DatabasePermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DatabasePermission</a>
Child elements	None

## Remarks

The **Administer** element indicates whether a user can perform administrative functions only on the specified database. The server administrator role can perform administrative functions on all databases contained by the instance.

The element that corresponds to the parent of **Administer** in the Analysis Management Objects (AMO) object model is [DatabasePermission](#).

# AggregateFunction Element (ASSL)

Article • 10/31/2023

Defines the type of aggregate function used by a [Measure](#) element.

## Syntax

XML

```
<Measure>
 ...
 <AggregateFunction>...</AggregateFunction>
 ...
</Measure>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Sum</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Measure</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

Value	Description
<i>Sum</i>	The measure is aggregated using the <b>Sum</b> function.
<i>Count</i>	The measure is aggregated using the <b>Count</b> function.
<i>Min</i>	The measure is aggregated using the <b>Min</b> function.
<i>Max</i>	The measure is aggregated using the <b>Max</b> function.
<i>DistinctCount</i>	The measure is aggregated using the <b>DistinctCount</b> function.
<i>None</i>	The measure is not aggregated.
<i>ByAccount</i>	The measure is aggregated by account.
<i>AverageOfChildren</i>	The measure is aggregated by returning the average of its children.
<i>FirstChild</i>	The measure is aggregated by returning its first child member.
<i>LastChild</i>	The measure is aggregated by returning its last child member.
<i>FirstNonEmpty</i>	The measure is aggregated by returning its first nonempty member.
<i>LastNonEmpty</i>	The measure is aggregated by returning its last nonempty member.

The enumeration that corresponds to the allowed values for **AggregateFunction** in the Analysis Management Objects (AMO) object model is [AggregationFunction](#).

# AggregationID Element (ASSL)

Article • 10/31/2023

Identifies the aggregation definition from the [AggregationDesign](#) element used to create the aggregation instance.

## Syntax

XML

```
<AggregationInstance>
 ...
 <AggregationID>...</AggregationID>
 ...
</AggregationInstance>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">AggregationInstance</a>
Child elements	None

## Remarks

If this element is missing or set to a blank string, the **AggregationInstance** represents a user-defined aggregation.

The element that corresponds to the parent of **AggregationID** in the Analysis Management Objects (AMO) object model is [AggregationInstance](#).

## See Also

 Yes

 No

# AggregationInstanceSource Element (ASSL)

Article • 10/31/2023

Identifies the source of data for user-defined aggregation instances bound to a [Partition](#) element.

## Syntax

XML

```
<Partition>
 ...
 <AggregationInstanceSource xsi:type="DataSourceViewBinding">...
</AggregationInstanceSource>
 ...
</Partition>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	<a href="#">DataSourceViewBinding</a>
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Partition</a>
Child elements	None

## Remarks

If this element is missing or set to a blank string, the data source view of the cube that owns the partition is used by default.

For additional information about the **Binding** type, including tables of Analysis Services Scripting Language (ASSL) objects of the **Binding** type and the inheritance hierarchy of **Binding** types, see [Binding Data Type \(ASSL\)](#).

Was this page helpful?

# AggregationPrefix Element (ASSL)

Article • 10/31/2023

Defines the common prefix to be used for aggregation names throughout the associated parent element.

## Syntax

XML

```
<Cube> <!-- or Database, MeasureGroup, Partition -->
...
<AggregationPrefix>...</AggregationPrefix>
...
</Database>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">Database</a> , <a href="#">MeasureGroup</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

Aggregation prefixes generate aggregation names in Analysis Services, and also generate table names in the relational database for aggregations stored in a relational OLAP (ROLAP) partition.

A fully expanded aggregation name has the following parts:

<*DatabasePrefix*><*CubePrefix*><*MeasureGroupPrefix*><*PartitionPrefix*>  
<*AggregationID*>

The first four parts of the aggregation name make up the aggregation prefix. The user provides the first four parts:

- *DatabasePrefix* represents the value of the **AggregationPrefix** element associated with a **Database** element.
- *CubePrefix* represents the value of the **AggregationPrefix** element associated with a **Cube** element.
- *MeasureGroupPrefix* represents the value of the **AggregationPrefix** element associated with a **MeasureGroup** element.
- *PartitionPrefix* represents the value of the **AggregationPrefix** element associated with a **Partition** element.

The fifth part of the name, *AggregationID*, is a system-defined ID, and users have no control over this part of the name.

The elements that correspond to the parents of **AggregationPrefix** in the Analysis Management Objects (AMO) object model are [Cube](#), [Database](#), [MeasureGroup](#), and [Partition](#).

# AggregationStorage Element (ASSL)

Article • 10/31/2023

Identifies the storage method for aggregations.

## Syntax

XML

```
<ProactiveCaching>
 ...
 <AggregationStorage>...</AggregationStorage>
 ...
</ProactiveCaching>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	ProactiveCaching
Child elements	None

## Remarks

The value of this element is limited to one of the following strings:

Value	Description
<i>Regular</i>	Aggregation data is stored in the default manner.
<i>MolapOnly</i>	Aggregation data is stored using multidimensional OLAP (MOLAP) storage only.

The *MolapOnly* option is available only for the [Partition](#) element.

The enumeration that corresponds to the allowed values for **AggregationStorage** in the Analysis Management Objects (AMO) object model is [ProactiveCachingAggregationStorage](#).

# AggregationType Element (ASSL)

Article • 10/31/2023

Defines the type of aggregation stored by the [Partition](#) element.

## Syntax

XML

```
<AggregationInstance>
 ...
 <AggregationType>...</AggregationType>
 ...
</AggregationInstance>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">AggregationInstance</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

Value	Description
<i>IndexedView</i>	The aggregation is stored in an indexed view.
<i>Table</i>	The aggregation is stored in a table.
<i>UserDefined</i>	The aggregation is user-defined.

The enumeration that corresponds to the allowed values for **AggregationType** in the Analysis Management Objects (AMO) object model is [AggregationInstance](#).

 Yes

 No

# AggregationUsage Element (ASSL)

Article • 10/31/2023

Controls how the Aggregation Designer in Analysis Services designs aggregations.

## Syntax

XML

```
<CubeAttribute>
 ...
 <AggregationUsage>...</AggregationUsage>
 ...
</CubeAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Default</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">CubeAttribute</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

Value	Description
<i>Full</i>	Every aggregation for the cube must include this attribute.
<i>None</i>	No aggregation for the cube should include this attribute.
<i>Unrestricted</i>	No restrictions are placed on the Aggregation Designer.
<i>Default</i>	The Aggregation Designer applies a default rule based on the type of attribute ( <i>Full</i> for keys, <i>Unrestricted</i> for others).

The enumeration that corresponds to the allowed values for **AggregationUsage** in the Analysis Management Objects (AMO) object model is [AggregationUsage](#).

# Algorithm Element (ASSL)

Article • 10/31/2023

Defines the algorithm used by a [MiningModel](#) element.

## Syntax

XML

```
<MiningModel>
 ...
 <Algorithm>...</Algorithm>
 ...
</MiningModel>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningModel</a>
Child elements	None

## Remarks

The value of the **Algorithm** element is a string that identifies the algorithm. For example, the string could be *Microsoft\_Naive\_Bayes*, *Microsoft\_Decision\_Trees*, or *Microsoft\_Clustering*. The string identifies algorithms supplied by and custom algorithms supplied by the user. Available values for the **Algorithm** element can be retrieved from the SERVICE\_NAME column of the DMSHEMA\_MINING\_SERVICES schema rowset.

The element that corresponds to the parent of **Algorithm** in the Analysis Management Objects (AMO) object model is [MiningModel](#). A closely related element in the AMO object model is [MiningModelAlgorithms](#).

---

# Alias Element (ASSL)

Article • 10/31/2023

Defines an alias for an [Account](#) element.

## Syntax

XML

```
<Aliases>
 <Alias>...</Alias>
</Aliases>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-n: Optional element that can occur more than once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Aliases</a>
Child elements	None

## Remarks

The value of the **Alias** element is used as an alternate name for the account defined by the **Account** parent element, and helps to identify the combination of account type and

aggregation function in a user interface.

The element that corresponds to the parent of the **Aliases** collection in the Analysis Management Objects (AMO) object model is [Account](#).

Child elements	None

## Remarks

The elements that correspond to the parents of **AllowDrillThrough** in the Analysis Management Objects (AMO) object model are [MiningModel](#), [MiningModelPermission](#), and [MiningStructurePermission](#).

## Drillthrough on Mining Structures

In SQL Server, you can define **AllowDrillthrough** permissions for mining structures as well as mining models. When you assign this permission to a role, any member of that role can query the data mining model, and return structure columns that were not included in the model. For example, you create a model that uses only these columns: customer key, customer income, and customer purchases. If you enable drillthrough on the model, users can return information in other columns of the mining structure, such as customer e-mails or names.

Therefore, to protect sensitive data, use caution when you add columns to the mining structure. Also, grant **AllowDrillthrough** permission on a structure only when it is required.

To drill through to structure columns, use a query with one of the following forms:

```
SELECT * FROM <structure>.CASES
```

or

```
SELECT StructureColumn('<structure-column-name>') FROM <model>.CASES
```

# AllowDuplicateNames Element (ASSL)

Article • 10/31/2023

Determines whether duplicate names are allowed in a [Hierarchy](#) element.

## Syntax

XML

```
<Hierarchy>
 ...
 <AllowDuplicateNames>...</AllowDuplicateNames>
 ...
</Hierarchy>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Hierarchy</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **AllowDuplicateNames** in the Analysis Management Objects (AMO) object model is [Hierarchy](#).

## See Also

[Properties \(ASSL\)](#)

 No

# AllowedRowsExpression Element (ASSL)

Article • 10/31/2023

Contains a Data Analysis expression (DAX), of Boolean type, which defines the contents of the parent element.

## Syntax

XML

```
<CellPermission> <!-- or StandardAction -->
...
<Expression>...</Expression>
...
</CellPermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CellPermission</a> , <a href="#">StandardAction</a>
Child elements	None

## Remarks

For the **CellPermission** element, the **Expression** element contains a logical MDX expression that identifies cells applicable to the rights indicated by the [Access](#) element of the **CellPermission** element. If the value of an **Expression** element for a **CellPermission** element is empty, the **CellPermission** element is ignored.

For the **StandardAction** element, the **Expression** element contains an MDX expression that represents the contents of the action. If the value of an **Expression** element for a **StandardAction** element is empty, the **StandardAction** element is ignored.

The elements that correspond to the parents in the Analysis Management Objects (AMO) object model are [CellPermission](#) and [StandardAction](#).

# AllowedSet Element (ASSL)

Article • 10/31/2023

Contains a set expression that defines the set of allowed permissions for a [Role](#) element on an attribute.

## Syntax

XML

```
<AttributePermission>
 ...
 <AllowedSet>...</AllowedSet>
 ...
</AttributePermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">AttributePermission</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **AllowedSet** in the Analysis Management Objects (AMO) object model is [AttributePermission](#).

## See Also

[Properties \(ASSL\)](#)

# Application Element (ASSL)

Article • 10/31/2023

Identifies the application associated with an [Action](#) element.

## Syntax

XML

```
<Action>
 ...
 <Application>...</Application>
 ...
</Action>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	Action or one of its derived elements: <a href="#">DrillThroughAction</a> , <a href="#">ReportAction</a> , <a href="#">StandardAction</a>
Child elements	None

## Remarks

The **Application** element can be used by client applications to determine which actions are applicable to a given client application. The client application is responsible for evaluating the value of this element.

The element that corresponds to the parent of **Application** in the Analysis Management Objects (AMO) object model is [Action](#).

# AssociatedMeasureGroupID Element (ASSL)

Article • 10/31/2023

Contains the ID of the [MeasureGroup](#) element associated with a [CalculationProperty](#) element or a [Kpi](#) element.

## Syntax

XML

```
<CalculationProperty> <!-- or Kpi -->
...
<AssociatedMeasureGroupID>...</AssociatedMeasureGroupID>
...
</CalculationProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">CalculationProperty</a> , <a href="#">Kpi</a>
Child elements	None

## Remarks

When applied to **CalculationProperty** elements, the **AssociatedMeasureGroupID** property applies to elements with a **CalculationType** of *Member*.

The elements that correspond to the parents of **AssociatedMeasureGroupID** in the Analysis Management Objects (AMO) object model are **CalculationProperty** and **Kpi**.

# AttributeAllMemberName Element (ASSL)

Article • 10/31/2023

Contains the caption, in the default language, for the All member of the dimension.

## Syntax

XML
<pre>&lt;Dimension&gt;   ...     &lt;AttributeAllMemberName&gt;...&lt;/AttributeAllMemberName&gt;   ... &lt;/Dimension&gt;</pre>

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">Dimension</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **AttributeAllMemberName** in the Analysis Management Objects (AMO) object model is [Dimension](#).

---

## Feedback

Was this page helpful?

 Yes

 No

# AttributeHierarchyDisplayFolder Element (ASSL)

Article • 10/31/2023

Identifies the folder in which to display the associated attribute hierarchy.

## Syntax

XML
<pre>&lt;DimensionAttribute&gt;   ...     &lt;AttributeHierarchyDisplayFolder&gt;...   &lt;/AttributeHierarchyDisplayFolder&gt;   ... &lt;/DimensionAttribute&gt;</pre>

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **AttributeHierarchyDisplayFolder** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

## See Also

[Properties \(ASSL\)](#)

## Feedback

Was this page helpful?

# AttributeHierarchyEnabled Element (ASSL)

Article • 10/31/2023

Determines whether an attribute hierarchy is enabled for the attribute.

## Syntax

```
XML

<DimensionAttribute><!-- or CubeAttribute -->
 ...
 <AttributeHierarchyEnabled>...</AttributeHierarchyEnabled>
 ...
</DimensionAttribute>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">CubeAttribute</a> , <a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The **AttributeHierarchyEnabled** element determines whether an attribute hierarchy is generated by Analysis Services for the attribute. If the attribute hierarchy is not enabled, then the attribute cannot be used in a user-defined hierarchy, nor can the attribute hierarchy be referenced in Multidimensional Expressions (MDX) statements.

The elements that correspond to the parents of **AttributeHierarchyEnabled** in the Analysis Management Objects (AMO) object model are [CubeAttribute](#) and [DimensionAttribute](#).

# AttributeHierarchyOptimizedState Element (ASSL)

Article • 10/31/2023

Determines the level of optimization applied to the attribute hierarchy.

## Syntax

```
XML

<DimensionAttribute> <!-- or CubeAttribute -->
 ...
 <AttributeHierarchyOptimizedState>...
 </AttributeHierarchyOptimizedState>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>FullyOptimized</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">CubeAttribute</a> , <a href="#">DimensionAttribute</a>
Child elements	None

# Remarks

The value of this element is limited to one of the strings in the following table.

 Expand table

Value	Description
<i>FullyOptimized</i>	The instance builds indexes for the attribute hierarchy to improve query performance.
<i>NotOptimized</i>	No additional indexes are built by the instance.

The enumeration corresponding to the allowed values for **AttributeHierarchyOptimizedState** in the Analysis Management Objects (AMO) object model is [OptimizationType](#). The elements that correspond to the parents of **AttributeHierarchyOptimizedState** in the AMO object model are [CubeAttribute](#) and [DimensionAttribute](#).

## See Also

 No

# AttributeHierarchyOrdered Element (ASSL)

Article • 10/31/2023

Determines whether the associated attribute hierarchy is ordered.

## Syntax

```
XML

<DimensionAttribute>
 ...
 <AttributeHierarchyOrdered>...</AttributeHierarchyOrdered>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **AttributeHierarchyOrdered** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# AttributeHierarchyVisible Element (ASSL)

Article • 10/31/2023

Determines whether the attribute hierarchy is visible to client applications.

## Syntax

```
XML

<DimensionAttribute> <!-- or CubeAttribute or PerspectiveAttribute -->
 ...
 <AttributeHierarchyVisible>...</AttributeHierarchyVisible>
 ...
</DimensionAttribute>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">CubeAttribute</a> , <a href="#">DimensionAttribute</a> , <a href="#">PerspectiveAttribute</a>
Child elements	None

## Remarks

The **AttributeHierarchyVisible** element determines whether the attribute hierarchy associated with the attribute is visible to client applications. If this element is set to **False**, the attribute hierarchy can still be used to create user-defined hierarchies and can be referenced by Multidimensional Expressions (MDX) statements.

The elements that correspond to the parents of **AttributeHierarchyVisible** in the Analysis Management Objects (AMO) object model are [CubeAttribute](#), [DimensionAttribute](#), and [PerspectiveAttribute](#).

Child elements	None

## Remarks

The **Collation** string consists of the locale identifier (LCID) and the comparison flag, separated by an underscore character. For example, Latin1\_General\_CI\_AS is an acceptable string.

The elements that correspond to the parents of **Collation** in the Analysis Management Objects (AMO) object model are [Cube](#), [Database](#), [DataItem](#), [Dimension](#), [MiningModel](#), and [MiningStructure](#).

# ColumnID Element (ColumnBinding) (ASSL)

Article • 10/31/2023

Contains the identifier (ID) of the column within the table to which the data item is bound.

## Syntax

XML

```
<ColumnBinding>
 ...
 <ColumnID>...</ColumnID>
 ...
</ColumnBinding>
```

## Element Characteristics

  Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element Relationships

  Expand table

Relationship	Element
Parent element	<a href="#">ColumnBinding</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **ColumnID** in the Analysis Management Objects (AMO) object model is [ColumnBinding](#).

# Condition Element (ASSL)

Article • 10/31/2023

Contains a Multidimensional Expressions (MDX) expression that determines whether the [Action](#) parent element applies to the target.

## Syntax

XML

```
<Action>
 ...
 <Condition>...</Condition>
 ...
</Action>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Action</a>
Child elements	None

## Remarks

The **Condition** element contains an MDX expression that evaluates to a Boolean value. If the expression returns **True**, then the **Action** applies to the target specified in the **Target** element. Otherwise, the **Action** is not applicable.

The element that corresponds to the parent of **Condition** in the Analysis Management Objects (AMO) object model is [Action](#).

# Content Element (ASSL)

Article • 10/31/2023

Describes the content of the column in the [MiningStructure](#) element.

## Syntax

XML

```
<ScalarMiningStructureColumn>
 ...
 <Content>...</Content>
 ...
</ScalarMiningStructureColumn>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent element	<a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

This enumeration describes the type of content represented by a mining structure column, and can be extended as needed by mining algorithm providers.

The values listed in the following table are typically supported by all mining algorithm providers.

  Expand table

Value	Description
<i>Discrete</i>	The column contains discrete values.
<i>Continuous</i>	The values for the column define a continuous set of numeric data.
<i>Discretized</i>	The values in the column represent groups (or buckets) of values derived from a continuous column.
<i>Ordered</i>	The values for the column define an ordered set.
<i>Cyclical</i>	The values for the column define a cyclical ordered set.
<i>Probability</i>	The values for the column specify a probability for the columns contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .
<i>Variance</i>	The values for the column specify a variance for the columns contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .
<i>StdDev</i>	The values for the column specify a standard deviation for the columns contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .
<i>ProbabilityVariance</i>	The values for the column specify a probability variance for the columns contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .
<i>ProbabilityStdDev</i>	The values for the column specify a probability standard deviation for the columns contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .
<i>Support</i>	The values for the column specify support information for the column contained in the <a href="#">ClassifiedColumns</a> element of the parent <b>ScalarMiningStructureColumn</b> .  Note: This column is provided as part of the standard for third party mining algorithm providers. Microsoft provided algorithms do not make use of this column.
<i>Key</i>	The column is a key column.

Value	Description
	Note: This content type is applicable only to key columns, in which the <b>IsKey</b> element is set to <b>True</b> .

In addition to these standard values, mining algorithm providers included with Analysis Services support the values in the following table.

[Expand table](#)

Value	Description
<i>Key Sequence</i>	The column is a key column, and the values for the column represent a sequence of events.  Note: This content type is applicable only to key columns, in which the <b>IsKey</b> element is set to <b>True</b> .
<i>Key Time</i>	The column is a key column, and the values for the column represent time measurement units.  Note: This content type is applicable only to key columns, in which the <b>IsKey</b> element is set to <b>True</b> .
<i>Sequence</i>	The values for the column represent a sequence of events.
<i>Time</i>	The values for the column represent time measurement units.

The enumeration corresponding to the allowed values for **Content** in the Analysis Management Objects (AMO) object model is [ScalarMiningStructureColumn](#).

 No

# CreatedTimestamp Element (ASSL)

Article • 10/31/2023

Contains the read-only creation timestamp of the parent element.

## Syntax

XML

```
<Assembly> <!-- or one of the elements listed below in the Element
Relationships table -->
...
<CreatedTimestamp>...</CreatedTimestamp>
...
</Assembly>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	DateTime
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Assembly</a> , <a href="#">Cube</a> , <a href="#">Database</a> , <a href="#">DataSource</a> , <a href="#">DataSourceView</a> , <a href="#">Dimension</a> , <a href="#">MdxScript</a> , <a href="#">MeasureGroup</a> , <a href="#">MiningModel</a> , <a href="#">MiningStructure</a> , <a href="#">Partition</a> , <a href="#">Permission</a> , <a href="#">Perspective</a>
Child elements	None

## Remarks

The **CreatedTimestamp** element contains a read-only **DateTime** value that represents the date and time that the object was created on a given instance of Analysis Services. The value of this element cannot be empty.

The elements that correspond to the parents of **CreatedTimestamp** in the Analysis Management Objects (AMO) object model are [Assembly](#), [Cube](#), [Database](#), [DataSource](#), [DataSourceView](#), [Dimension](#), [MdxScript](#), [MeasureGroup](#), [MiningModel](#), [MiningStructure](#), [Partition](#), [Permission](#), and [Perspective](#).

# CurrentStorageMode Element (ASSL)

Article • 10/31/2023

Determines the current storage mode for the parent element.

## Syntax

XML

```
<Dimension> <!-- or Partition -->
 <CurrentStorageMode>...</CurrentStorageMode>
</Dimension>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ROLAP</i>
Cardinality	0-1: Optional element that can occur once or not at all.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Dimension</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

The **CurrentStorageMode** element indicates the storage mode currently in use for proactive caching purposes, and applies to all attributes of the parent element.

The value of this element is limited to one of the strings in the following table.

[Expand table](#)

Value	Description
<i>MOLAP</i>	The parent uses multidimensional OLAP (MOLAP) storage.
<i>ROLAP</i>	The parent uses relational OLAP (ROLAP) storage.
<i>HOLAP</i>	The parent uses hybrid OLAP (HOLAP) storage.
Note: This value is only valid for <a href="#">Partition</a> parent elements.	

The enumeration corresponding to the allowed values **CurrentStorageMode** in the Analysis Management Objects (AMO) object model is [StorageMode](#).

 No

# CurrentTimeMember Element (ASSL)

Article • 10/31/2023

Defines the current member of a time dimension associated with a [Kpi](#) element.

## Syntax

XML

```
<Kpi>
 ...
 <CurrentTimeMember>...</CurrentTimeMember>
 ...
</AggregationDimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Kpi</a>
Child elements	None

## Remarks

The value of this element is a Multidimensional Expressions (MDX) statement that evaluates to a single member in a time dimension, used to retrieve the current timeframe when evaluating the key performance indicator (KPI).

The element that corresponds to the parent of **CurrentTimeMember** in the Analysis Management Objects (AMO) object model is [Kpi](#).

# DataType Element (ASSL)

Article • 10/31/2023

Defines the data type of the associated element.

## Syntax

XML

```
<DataItem> <!-- or Measure -->
 ...
 <DataType>...</DataType>
 ...
</DataItem>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataItem</a> , <a href="#">Measure</a>
Child elements	None

## Remarks

The values for **DataType** are defined in the **System.Data.OleDb.OleDbType** enumeration. However, only the enumeration values in the following table are valid in the **DataType** element.

[ ] Expand table

Value	Description
<i>BigInt</i>	A 64-bit signed integer. This data type maps to the <b>Int64</b> data type in .NET Framework and the <b>DBTYPE_I8</b> data type in OLE DB.
<i>Bool</i>	A Boolean value. This data type maps to the <b>Boolean</b> data type in the .NET Framework and the <b>DBTYPE_BOOL</b> data type in OLE DB.
<i>Currency</i>	A currency value ranging from -2 <sup>63</sup> (or -922,337,203,685,477.5808) to 2 <sup>63</sup> -1 (or +922,337,203,685,477.5807) with an accuracy to a ten-thousandth of a currency unit. This data type maps to the <b>Decimal</b> data type in the .NET Framework and the <b>DBTYPE_CY</b> data type in OLE DB.
<i>Date</i>	Date data, stored as a double-precision floating point number. The whole portion is the number of days since December 30, 1899, while the fractional portion is a fraction of a day. This data type maps to the <b>DateTime</b> data type in the .NET Framework and the <b>DBTYPE_DATE</b> data type in OLE DB.
<i>Double</i>	A double-precision floating point number within the range of -1.79E +308 through 1.79E +308. This data type maps to the <b>Double</b> data type in the .NET Framework and the <b>DBTYPE_R8</b> data type in OLE DB.
<i>Integer</i>	A 32-bit signed integer. This data type maps to the <b>Int32</b> data type in the .NET Framework and the <b>DBTYPE_I4</b> data type in OLE DB.
<i>Single</i>	A single-precision floating point number within the range of -3.40E +38 through 3.40E +38. This data type maps to the <b>Single</b> data type in .NET Framework and the <b>DBTYPE_R4</b> data type in OLE DB.
<i>SmallInt</i>	A 16-bit signed integer. This data type maps to the <b>Int16</b> data type in the .NET Framework and the <b>DBTYPE_I2</b> data type in OLE DB.
<i>TinyInt</i>	An 8-bit signed integer. This data type maps to the <b>SByte</b> data type in the .NET Framework and the <b>DBTYPE_I1</b> data type in OLE DB.
<i>UnsignedBigInt</i>	A 64-bit unsigned integer. This data type maps to the <b>UInt64</b> data type in .NET Framework and the <b>DBTYPE_UI8</b> data type in OLE DB.
<i>UnsignedInt</i>	A 32-bit unsigned integer. This data type maps to the <b>UInt32</b> data type in the .NET Framework and the <b>DBTYPE_UI4</b> data type in OLE DB.
<i>UnsignedSmallInt</i>	A 16-bit unsigned integer. This data type maps to the <b>UInt16</b> data type in the .NET Framework and the <b>DBTYPE_UI2</b> data type in OLE DB.

Value	Description
<i>WChar</i>	A null-terminated stream of Unicode characters. This data type maps to the <b>String</b> data type in the .NET Framework and the DBTYPE_WSTR data type in OLE DB.
<i>Inherited</i>	The data type of the <b>DataItem</b> contained in the <a href="#">Source</a> element of the <b>Measure</b> element.  Note: Applicable only to <b>Measure</b> elements.

# DefaultMember Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression that identifies the default member of the parent element.

## Syntax

XML

```
<AttributePermission> <!-- or DimensionAttribute,
ManyToManyMeasureGroupDimension, PerspectiveAttribute -->
 ...
 <DefaultMember>...</DefaultMember>
 ...
</AttributePermission>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">AttributePermission</a> , <a href="#">DimensionAttribute</a> , <a href="#">ManyToManyMeasureGroupDimension</a> , <a href="#">PerspectiveAttribute</a>
Child elements	None

## Remarks

The **DefaultMember** element defines the default member for the parent element. If **DefaultMember** is not specified or is set to an empty string, Analysis Services chooses a member to use as the default member.

For **ManyToManyMeasureGroupDimension** elements, the **DefaultMember** element contains an MDX expression that specifies a member in the dimension identified in the **CubeDimensionID** element of the **ManyToManyMeasureGroupDimension**. The MDX expression is similar to the **StrToMember** MDX function with the **CONSTRAINED** keyword, in that it cannot include MDX or user-defined functions.

The elements that correspond to the parents of **DefaultMember** in the Analysis Management Objects (AMO) object model are [AttributePermission](#), [DimensionAttribute](#), and [PerspectiveAttribute](#).

# DefaultScript Element (ASSL)

Article • 12/09/2022

Identifies the default [MdxScript](#) element in the [MdxScripts](#) collection.

## Syntax

XML

```
<MdxScript>
 ...
 <DefaultScript>...</DefaultScript>
 ...
</MdxScript>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">MdxScript</a>
Child elements	None

## Remarks

Setting the value of **DefaultScript** to **True** for one script sets the value of **DefaultScript** to **False** for all other **MdxScript** elements in the **MdxScripts** collection.

The element that corresponds to the parent of **DefaultScript** in the Analysis Management Objects (AMO) object model is [MdxScript](#).

Yes

No

# DefaultValue Element (ASSL)

Article • 12/09/2022

Contains the read-only default value of the associated [ServerProperty](#) element.

## Syntax

XML

```
<ServerProperty>
 ...
 <DefaultValue> </DefaultValue>
 ...
</ServerProperty>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	Any simpleType
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">ServerProperty</a>
Child elements	None

## Remarks

This element contains the read-only installation default value of the **ServerProperty** for the current instance of Analysis Services. The default value is supplied by the instance, and typically cannot be changed.

The element that corresponds to the parent of **DefaultValue** in the Analysis Management Objects (AMO) object model is [ServerProperty](#).

# DeniedSet Element (ASSL)

Article • 12/09/2022

Contains a set expression that defines the list of permissions that are denied on the associated attribute.

## Syntax

XML

```
<AttributePermission>
 ...
 <DeniedSet>...</DeniedSet>
 ...
</AttributePermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">AttributePermission</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **DeniedSet** in the Analysis Management Objects (AMO) object model is [AttributePermission](#).

 No

# DependsOnDimensionID Element (ASSL)

Article • 12/09/2022

Contains the identifier (ID) of another dimension on which the parent dimension depends.

## Syntax

XML

```
<Dimension>
 ...
 <DependsOnDimensionID>...</DependsOnDimensionID>
 ...
</Dimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Dimension</a>
Child elements	None

## Remarks

The **DependsOnDimensionID** element is used by a dependent dimension to identify the dimension on which it depends.

The element that corresponds to the parent of **DependsOnDimensionID** in the Analysis Management Objects (AMO) object model is [Dimension](#).

## See Also

[Properties \(ASSL\)](#)

 No

# Description Element (ASSL)

Article • 12/09/2022

Contains the description of the parent element.

## Syntax

XML

```
<Action> <!-- or one of the elements listed below in the Element
Relationships table -->
...
<Description>...</Description>
...
</Action>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that occurs once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	Action, Aggregation, AggregationDesign, Assembly, AttributePermission, CalculationProperty, CellPermission, Cube, CubeDimensionPermission, Database, DataSource, DataSourceView, Dimension, DimensionAttribute, Hierarchy, Kpi, Level, MdxScript, Measure, MeasureGroup, MiningModel, MiningModelColumn, MiningStructure, MiningStructureColumn, Partition, Permission, Perspective, Role, Server, Trace, Translation

Relationship	Element
Child elements	None

## Remarks

The value of a **Description** element has the following restrictions:

- The value cannot contain leading or trailing spaces. If leading or trailing spaces are included in the value of a **Description** element, those spaces will be implicitly removed by Analysis Services.
- The value cannot contain control characters. If control characters are included in the value of a **Description** element, those characters will be implicitly removed by Analysis Services.

## Feedback

Was this page helpful?

 Yes

 No

# DiscretizationBucketCount Element (ASSL)

Article • 12/09/2022

Contains the number of buckets into which to discretize.

## Syntax

```
XML

<DimensionAttribute> <!-- or ScalarMiningStructureColumn -->
 ...
 <DiscretizationBucketCount>...</DiscretizationBucketCount>
 ...
</DimensionAttribute>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	Integer
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a> , <a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

The value of the **DiscretizationBucketCount** element determines how many groups or "buckets" are created when values for the **DimensionAttribute** or **ScalarMiningStructureColumn** are discretized, or organized into a specific set of groups. If the element is not specified, or if zero is specified for the value of the element, Analysis Services creates an appropriate number of groups depending on the discretization method.

The elements that correspond to the parents of **DiscretizationBucketCount** in the Analysis Management Objects (AMO) object model are **DimensionAttribute** and **ScalarMiningStructureColumn**.

---

## Feedback

Was this page helpful?

 No

# DiscretizationMethod Element (ASSL)

Article • 12/09/2022

Defines the method to be used for discretization.

## Syntax

XML

```
<DimensionAttribute> <!-- or ScalarMiningStructureColumn -->
 ...
 <DiscretizationMethod>...</DiscretizationMethod>
 ...
</DimensionAttribute>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">DimensionAttribute</a> , <a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

The value of the **DiscretizationMethod** element determines how values for the **DimensionAttribute** or **ScalarMiningStructureColumn** are discretized, or organized into a specific set of groups.

The value of this element is limited to one of the strings in the following table.

  Expand table

Value	Description
<i>Automatic</i>	Equivalent to the AUTOMATIC discretization method for mining structure columns.
<i>EqualAreas</i>	Equivalent to the EQUAL_AREAS discretization method for mining structure columns.
<i>Clusters</i>	Equivalent to the CLUSTERS discretization method for mining structure columns.
<i>Thresholds</i>	Equivalent to the THRESHOLDS discretization method for mining structure columns.
<i>EqualRanges</i>	Equivalent to the EQUAL_RANGES discretization method for mining structure columns.

The enumeration corresponding to the allowed values for **DiscretizationMethod** in the Analysis Management Objects (AMO) object model is [DiscretizationMethod](#).

# DisplayFlag Element (ASSL)

Article • 12/09/2022

Contains a read-only hint that indicates whether user interface components should display the associated [ServerProperty](#) element.

## Syntax

XML

```
<ServerProperty>
 ...
 <DisplayFlag>...</DisplayFlag>
 ...
</ServerProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">ServerProperty</a>
Child elements	None

## Remarks

The element corresponding to the parent of `DisplayFlag` in the Analysis Management Objects (AMO) object model is [ServerProperty](#).

# DisplayFolder Element (ASSL)

Article • 12/09/2022

Specifies the folder in which to list the parent element. Analysis Services applications for developers and administrators may support the use of display folders to categorize multiple elements visually.

## Syntax

XML

```
<CalculationProperty> <!-- or Hierarchy, Kpi, Measure, Translation -->
...
<DisplayFolder>...</DisplayFolder>
...
</CalculationProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CalculationProperty</a> , <a href="#">Hierarchy</a> , <a href="#">Kpi</a> , <a href="#">Measure</a> , <a href="#">Translation</a>
Child elements	None

## Remarks

In larger cubes, there may be hundreds of measures and hierarchies. The **DisplayFolder** property defines user appearance on the client. The value of the **DisplayFolder** property can contain any one of the following options:

- Be empty, denoting that the measure does not belong to a folder.
- Contain a single folder name, denoting that the measure should be rendered as belonging to a folder with the same name.
- Contain multiple folder names separated by a backslash (\), denoting an embedded folder hierarchy.

The **DisplayFolder** property applies to **CalculationProperty** elements only if the value of **CalculationType** is set to *Member*.

The elements that correspond to the parents of **DisplayFolder** in the Analysis Management Objects (AMO) object model are **CalculationProperty**, **Hierarchy**, **Kpi**, **Measure**, and **Translation**.

# Distribution Element (ASSL)

Article • 12/09/2022

Contains a provider-specific value that describes how scalar values are distributed within a column of a [MiningStructure](#) element.

## Syntax

XML

```
<ScalarMiningStructureColumn>
 ...
 <Distribution>...</Distribution>
 ...
</ScalarMiningStructureColumn>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

The values available for the **Distribution** element, such as *Normal* or *Uniform*, are specific to each mining algorithm provider. For more information about valid **Distribution** values, see the mining algorithm provider documentation.

The element corresponding to the parent of **Distribution** in the Analysis Management Objects (AMO) object model is [ScalarMiningStructureColumn](#).

# Edition Element (ASSL)

Article • 12/09/2022

Contains the read-only edition of the instance of represented by the [Server](#) element.

## Syntax

XML

```
<Server>
 ...
 <Edition>...</Edition>
 ...
</Server>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Server</a>
Child elements	None

## Remarks

The **Edition** element describes which edition of Analysis Services is installed. The value of this element is limited to one of the strings in the following table.

[Expand table](#)

Value	Description
<i>Standard</i>	Standard edition for 32-bit processors.
<i>Enterprise</i>	Enterprise edition for 32-bit processors.
<i>EnterpriseCore</i>	Enterprise edition: Core-based Licensing for 32-bit processors.
<i>BusinessIntelligence</i>	Business Intelligence edition for 32-bit processors.
<i>Developer</i>	Developer edition for 32-bit processors
<i>Evaluation</i>	Evaluation edition for 64-bit processors.
<i>Local</i>	Local edition for 32-bit processors.
<i>Standard64</i>	Standard edition for 64-bit processors.
<i>Enterprise64</i>	Enterprise edition for 64-bit processors.
<i>EnterpriseCore64</i>	Enterprise edition: Core-based Licensing for 64-bit processors.
<i>BusinessIntelligence64</i>	Business Intelligence edition for 64-bit processors.
<i>Developer64</i>	Developer edition for 64-bit processors
<i>Evaluation64</i>	Evaluation edition for 64-bit processors.
<i>Local64</i>	Local edition for 64-bit processors.

The enumeration corresponding to the allowed values for **ServerEdition** in the Analysis Management Objects (AMO) object model is [ServerEdition](#).

# Expression Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression that defines the contents of the parent element.

## Syntax

XML

```
<CellPermission> <!-- or StandardAction -->
...
<Expression>...</Expression>
...
</CellPermission>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">CellPermission</a> , <a href="#">StandardAction</a>
Child elements	None

## Remarks

For the **CellPermission** element, the **Expression** element contains a logical MDX expression that identifies cells applicable to the rights indicated by the [Access](#) element of the **CellPermission** element. If the value of an **Expression** element for a **CellPermission** element is empty, the **CellPermission** element is ignored.

For the **StandardAction** element, the **Expression** element contains an MDX expression that represents the contents of the action. If the value of an **Expression** element for a **StandardAction** element is empty, the **StandardAction** element is ignored.

The elements that correspond to the parents in the Analysis Management Objects (AMO) object model are [CellPermission](#) and [StandardAction](#).

# FiscalYearName Element (ASSL)

Article • 12/09/2022

Defines the naming convention for the name of the fiscal year for a [TimeBinding](#) element.

## Syntax

XML

```
<TimeBinding>
 ...
 <FiscalYearName>...</FiscalYearName>
 ...
</TimeBinding>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>NextCalendarYearName</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">TimeBinding</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

[\[+\] Expand table](#)

Value	Description
<i>CalendarYearName</i>	Assigns the fiscal year the name of the current calendar year.
<i>NextCalendarYearName</i>	Assigns the fiscal year the name of the next calendar year.

The enumeration that corresponds to the allowed values for **FiscalYearName** in the Analysis Management Objects (AMO) object model is [FiscalYearName](#).

# FoldingParameters Element (ASSL)

Article • 12/09/2022

Specifies the parameters used by the Analysis Services server when it performs cross-validation of mining models.

## ⓘ Note

These parameters are for internal use only. The information provided here is for reference only.

## Syntax

### XML

```
<MiningModel>
 ...
 <ddl100_100:FoldingParameters>...
 <ddl100_100:FoldIndex>...</ddl100_100:FoldIndex>
 <ddl100_100:FoldCount>...</ddl100_100:FoldCount>
 <ddl100_100:MaxCases>...</ddl100_100:MAxCases>
 <ddl100_100:FoldTargetAttribute>...</ddl100_100:FoldTargetAttribute>
 ...</ddl100_100:FoldingParameters>
</MiningStructure>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
<i>FoldIndex</i>	Integer that indicates the starting position of the partition that is used for cross-validation.
<i>FoldCount</i>	Integer that indicates the number of partitions in the model after cross-validation.
<i>MaxCases</i>	Integer that indicates how many model cases are used for cross-validation.  A value of 0 indicates that all cases are used.

Characteristic	Description
<i>FoldTargetAttribute</i>	String that indicates the ID of the model column that contains the predictable attribute.

## Element Relationships

[Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningModel</a>
Child elements	<i>FoldIndex</i> <i>FoldCount</i> <i>MaxCases</i> <i>FoldTargetAttribute</i>

## Remarks

These properties are for internal use only, and are not supported for use in DDL statements.

 No

# FontFlags Element (ASSL)

Article • 12/09/2022

Describes font-related display characteristics of the [CalculationProperty](#) or [Measure](#) parent element.

## Syntax

XML

```
<CalculationProperty> <!-- or Measure -->
...
<FontFlags>...</FontFlags>
...
</CalculationProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CalculationProperty</a> , <a href="#">Measure</a>
Child elements	None

## Remarks

The **FontFlags** property contains a Multidimensional Expressions (MDX) expression and applies to **CalculationProperty** elements that have a **CalculationType** of *Member* or *Cells*.

The elements that correspond to the parents of **FontFlags** in the Analysis Management Objects (AMO) object model are **CalculationProperty** and **Measure**.

# Format Element (ASSL)

Article • 12/09/2022

Contains the required format of the [DataItem](#) element.

## Syntax

XML

```
<DataItem>
 ...
 <Format>...</Format>
 ...
</DataItem>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">DataItem</a>
Child elements	None

## Remarks

Allowed values for the **Format** element are Microsoft Office Excel formats, and the strings *TrimRight*, *TrimLeft*, *TrimAll*, and *TrimNone*. For trimming, *TrimRight* is the default.

The value of this element is limited to one of the strings in the following table.

 Expand table

Value	Description
Any Excel format string	Data is formatted according to the specified named or custom format string. Any format string that Excel supports can be supplied.
<i>TrimAll</i>	Data is trimmed on the left and right.
<i>TrimLeft</i>	Data is trimmed on the left.
<i>TrimNone</i>	Data is not trimmed.
<i>TrimRight</i>	Data is trimmed on the right.

The element that corresponds to the parent of **Format** in the Analysis Management Objects (AMO) object model is [Dataltem](#).

# FormatString Element (ASSL)

Article • 12/09/2022

Describes the display format for a [CalculationProperty](#) element or a [Measure](#) element.

## Syntax

XML

```
<CalculationProperty> <!-- or Measure -->
 ...
 <FormatString>...</FormatString>
 ...
</CalculationProperty>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CalculationProperty</a> , <a href="#">Measure</a>
Child elements	None

## Remarks

The **FormatString** property contains a Multidimensional Expressions (MDX) expression. In the case of **CalculationProperty** elements, it applies to elements with a **CalculationType** of *Member* or *Cells*.

The elements that correspond to the parents of **FormatString** in the Analysis Management Objects (AMO) object model are **CalculationProperty** and **Measure**.

---

# HideMemberIf Element (ASSL)

Article • 12/09/2022

Indicates whether and when a member in a level should be hidden from client applications.

## Syntax

XML

```
<Level>
 ...
 <HideMemberIf>...</HideMemberIf>
 ...
</Level>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Never</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Level</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

[Expand table](#)

Value	Description
<i>Never</i>	Members are never hidden.
<i>OnlyChildWithNoName</i>	A member is hidden when it is the only child of its parent and its name is empty.
<i>OnlyChildWithParentName</i>	A member is hidden when it is the only child of its parent and its name is identical to that of its parent.
<i>NoName</i>	A member is hidden when its name is empty.
<i>ParentName</i>	A member is hidden when its name is identical to that of its parent.

The enumeration that corresponds to the allowed values for `HideMemberIf` in the Analysis Management Objects (AMO) object model is [HidelfValue](#).

# HoldoutActualSize Element

Article • 12/09/2022

Indicates the actual size, after processing, of the holdout partition that contains the test set of a [MiningStructure](#) element. The remaining cases in the data set are used for training. This property is read-only.

## Syntax

XML

```
<MiningStructure>
 ...
 <ddl100_100:HoldoutActualSize>...</ddl100_100:HoldoutActualSize>
 ...
</MiningStructure>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Read-only integer value.
Default value	Not applicable
Cardinality	0-1: Optional element that can occur one time and only one time.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">MiningStructure</a>
Child elements	None

## Remarks

The value for **HoldoutActualSize** depends on the source data, and on the values for **HoldoutMaxCases**, **HoldoutMaxPercent**, and **HoldoutSeed**. Therefore, the value for **HoldoutActualSize** is not available until after Analysis Services processes the mining structure.

The element that corresponds to the parent of **HoldoutActualSize** in the Analysis Management Objects (AMO) object model is [MiningStructure](#).

#### Note

In SQL Server 2005, Analysis Services did not support the use of holdout partitions on a mining structure. Therefore, Analysis Services Scripting Language (ASSL) statements that contain one of the holdout parameters, **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize**, cannot be used in SQL Server 2005. If you use one of these holdout parameters in an ASSL statement in SQL Server 2005, Analysis Services will return an error.

## See Also

 Yes

 No

# HoldoutMaxCases Element

Article • 12/09/2022

Specifies the maximum number of cases in the data source to be used for the holdout partition that contains the test set of a [MiningStructure](#) element. The remaining cases in the data set are used for training. A value of 0 indicates that there is no limit to the number of cases that can be held out as the test set.

## Syntax

XML
<pre>&lt;MiningStructure&gt;   ...   &lt;ddl100_100:HoldoutMaxCases&gt;...&lt;/ddl100_100:HoldoutMaxCases&gt;   ... &lt;/MiningStructure&gt;</pre>

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	Integer greater than 0.
Default value	0
Cardinality	0-1: Optional element that can occur one time and one time only.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningStructure</a>
Child elements	None

# Remarks

If you specify values for both **HoldoutMaxPercent** and **HoldoutMaxCases**, the algorithm limits the test set to the smaller of the two values.

If **HoldoutMaxCases** is set to the default of 0, and a value has not been set for **HoldoutMaxPercent**, the algorithm uses the entire data set for training.

The new properties **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize** are available only in SQL Server 2008 and later versions. Therefore, you must prefix these properties with the new namespace as shown in the syntax description, or Analysis Services will return an error.

## ⓘ Note

In SQL Server 2005, Analysis Services did not support the use of holdout partitions on a mining structure. Therefore, Analysis Services Scripting Language (ASSL) statements that contain one of the holdout parameters, **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize**, cannot be used in SQL Server 2005. If you use one of these holdout parameters in an ASSL statement in SQL Server 2005, Analysis Services will return an error.

The element that corresponds to the parent of **HoldoutMaxCases** in the Analysis Management Objects (AMO) object model is [MiningStructure](#).

# HoldoutMaxPercent Element

Article • 12/09/2022

Specifies the maximum percentage of cases in the data source that will be used for the holdout partition that contains the test set of a [MiningStructure](#) element. The remaining cases are used for training. A value of 0 indicates that there is no limit to the number of cases that can be held out as the test set.

## Syntax

XML
<pre>&lt;MiningStructure&gt;   ...   &lt;ddl100_100:HoldoutMaxPercent&gt;...&lt;/ddl100_100:HoldoutMaxPercent&gt;   ... &lt;/MiningStructure&gt;</pre>

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer between 0 and 99.
Default value	30
Cardinality	0-1: Optional element that can occur one time and one time only.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">MiningStructure</a>
Child elements	None

# Remarks

If you specify values for both **HoldoutMaxPercent** and **HoldoutMaxCases**, the algorithm limits the test set to the smaller of the two values.

If **HoldoutMaxCases** is set to the default of 0, and a value has not been set for **HoldoutMaxPercent**, the algorithm uses the complete data set for training.

The new properties **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize** are available only in SQL Server 2008 and later versions. Therefore, you must prefix these properties by using the new namespace as shown in the syntax description, or Analysis Services will return an error.

## ⓘ Note

In SQL Server 2005, Analysis Services did not support the use of holdout partitions on a mining structure. Therefore, Analysis Services Scripting Language (ASSL) statements that contain one of the holdout parameters, **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize**, cannot be used in SQL Server 2005. If you use one of these holdout parameters in an ASSL statement in SQL Server 2005, Analysis Services will return an error.

The element that corresponds to the parent of **HoldoutMaxPercent** in the Analysis Management Objects (AMO) object model is [MiningStructure](#).

 No

# HoldoutSeed Element

Article • 12/09/2022

Specifies the seed for a repeatable holdout partition that contains the test set of a [MiningStructure](#) element. This seed ensures that the model content remains the same during reprocessing. If unspecified or set to 0, Analysis Services creates a seed by using a hashing algorithm on the name of the mining structure.

## Syntax

XML

```
<MiningStructure>
 ...
 <ddl100_100:HoldoutSeed>...</ddl100_100:HoldoutSeed>
 ...
</MiningStructure>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Long
Default value	0
Cardinality	0-1: Optional element that can occur one time and one time only.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">MiningStructure</a>
Child elements	None

## Remarks

When you first create a mining structure, the ID and the name are the same. However, you can change the name of the mining structure. Therefore, if you want to ensure that the partition is repeatable, you should not rely on the seed created by the name, but should explicitly set a seed.

Additionally, when you create a copy of a mining structure by using the **EXPORT** statement, Analysis Services will retain the name for the new mining structure but will automatically generate a new ID. Therefore, it is possible to have two mining structures that share the same name but have different IDs. Any two mining structures that have the same name will have the same seed. However, as the partitioning of the data also depends on the source data, the actual contents of the partitions in each structure may be different.

The new properties **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize** are available only in SQL Server 2008 and later versions. Therefore, you must prefix these properties with the new namespace as shown in the syntax description, or Analysis Services will return an error.

**Note** In SQL Server 2005, Analysis Services did not support the use of holdout partitions on a mining structure. Therefore, Analysis Services Scripting Language (ASSL) statements that contain the holdout parameters **HoldoutMaxCases**, **HoldoutMaxPercent**, **HoldoutSeed**, or **HoldoutActualSize** cannot be used in SQL Server 2005. If you use one of these holdout parameters in an ASSL statement in SQL Server 2005, Analysis Services will return an error.

The element that corresponds to the parent of **HoldoutSeed** in the Analysis Management Objects (AMO) object model is [MiningStructure](#).

# ID Element (ASSL)

Article • 12/09/2022

Contains the unique identifier (ID) of the parent element.

## Syntax

XML

```
<Action> <!-- or one of the elements listed in the Element Relationships
table -->
...
<ID>...</ID>
...
</Action>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (up to 100 characters)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	Action, Aggregation, AggregationDesign, Assembly, Cube, CubeBinding, CubeDimension, Database, DataSource, DataSourceView, Dimension, DimensionAttribute, Hierarchy, Kpi, Level, MdxScript, Measure, MeasureGroup, MeasureGroupBinding, MiningModel, MiningModelColumn, MiningStructure, MiningStructureColumn, Partition, Permission, Perspective, Role, Server, Trace
Child	None

Relationship	Element
	elements

## Remarks

Every major object in Analysis Services has an **ID** element as a property. The value of an **ID** element has the following restrictions:

- The value cannot contain leading or trailing spaces. Analysis Services will implicitly remove leading or trailing spaces from the value of an **ID** element.
- The value cannot contain control characters. Analysis Services will implicitly remove control characters from the value of an **ID** element.
- The following reserved values cannot be used:
  - AUX
  - CLOCK\$
  - COM1 through COM9 (COM1, COM2, COM3, and so on)
  - CON
  - LPT1 through LPT9 (LPT1, LPT2, LPT3, and so on)
  - NUL
  - PRN

The following table lists additional characters that cannot be used within the value of an **ID** element, depending on the parent element.

[\[+\] Expand table](#)

Parent element	Invalid Characters
Server	The name must follow the rules for Windows computer names. IP addresses are not valid.
DataSource	:/\*\&#124;?"()[]{}<>`
Level, Attribute Element	,;':/\*\&#124;?"&%\$!+=[]{}<>`
All other parent	,;':/\*\&#124;?"&%\$!+=()[]{}<>`

# IgnoreUnrelatedDimensions Element (ASSL)

Article • 12/09/2022

Determines whether unrelated dimensions are forced to their top level when members of dimensions that are unrelated to the measure group are included in a query.

## Syntax

XML

```
<MeasureGroup>
 ...
 <IgnoreUnrelatedDimensions>...</IgnoreUnrelatedDimensions>
 ...
</MeasureGroup>
```

## Element Characteristics

[] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[] Expand table

Relationship	Element
Parent element	<a href="#">MeasureGroup</a>
Child elements	None

## Remarks

When **IgnoreUnrelatedDimensions** is **true**, unrelated dimensions are forced to their top level; when the value is **false**, dimensions are not forced to their top level. This property is similar to the Multidimensional Expressions (MDX) `ValidMeasurefunction`.

The element that corresponds to the parent of **IgnoreUnrelatedDimensions** in the Analysis Management Objects (AMO) object model is [MeasureGroup](#).

# ImpersonationInfo Element (ASSL)

Article • 12/09/2022

Contains the information that is used to determine impersonation behavior when accessing or executing an assembly.

## Syntax

XML

```
<Assembly> <!-- or one of the elements listed in the Element Relationships
table -->
 <ImpersonationInfo>
 <!-- Child elements are only those that are inherited from
 ImpersonationInfo -->
 </ImpersonationInfo>
</Assembly>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	<a href="#">ImpersonationInfo</a>
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Assembly</a> , <a href="#">DataSource</a>
Child elements	None

# ImpersonationInfoSecurity Element (ASSL)

Article • 12/09/2022

Contains a read-only value that indicates if any changes were made to the security credentials that are supplied in the [ImpersonationInfo](#) data type.

## Syntax

XML

```
<ImpersonationInfo>
 ...
 <ImpersonationInfoSecurity>...</ImpersonationInfoSecurity>
 ...
</ImpersonationInfo>...
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ImpersonationInfo</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

[Expand table](#)

Value	Description
<i>PasswordRemoved</i>	Password information has been removed from the supplied security credentials.
<i>Unchanged</i>	No changes have been made to the supplied security credentials.

The enumeration that corresponds to the allowed values for **ImpersonationInfoSecurity** in the Analysis Management Objects (AMO) object model is [ImpersonationInfoSecurity](#).

# ImpersonationMode Element (ASSL)

Article • 12/09/2022

Contains a value that indicates the method of impersonation for elements that are derived from the [ImpersonationInfo](#) data type.

## Syntax

XML

```
<ImpersonationInfo>
 ...
 <ImpersonationMode>...</ImpersonationMode>
 ...
</ImpersonationInfo>...
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Default</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ImpersonationInfo</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

[\[\] Expand table](#)

Value	Description
<i>Default</i>	The parent uses the impersonation method that is most appropriate for the context in which impersonation is used.
<i>ImpersonateAccount</i>	The parent uses the credentials of the user account that is specified in the parent element.
<i>ImpersonateAnonymous</i>	The parent uses the credentials of an anonymous user.
<i>ImpersonateCurrentUser</i>	The parent uses the credentials of the current user.
<i>ImpersonateServiceAccount</i>	The parent uses the credentials of the service account that is associated with the instance of Analysis Services.

The enumeration that corresponds to the allowed values for **ImpersonationMode** in the Analysis Management Objects (AMO) object model is [ImpersonationLevel](#).

# InstanceSelection Element (ASSL)

Article • 12/09/2022

Provides a hint to client applications to suggest how a list of items should be displayed, based on the expected number of items in the list.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <InstanceSelection>...</InstanceSelection>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The value of this element is limited to one of the following strings:

[Expand table](#)

Value	Description
<i>None</i>	Do not display a selection list. Allow users to enter values directly.
<i>DropDown</i>	The number of items is small enough to display in a dropdown list.
<i>List</i>	The number of items is too large for a dropdown list but does not require filtering.
<i>FilteredList</i>	The number of items is large enough to require users to filter the items to be displayed.
<i>MandatoryFilter</i>	The number of items is so large that the display must always be filtered.

The enumeration that corresponds to the allowed values for `InstanceSelection` in the Analysis Management Objects (AMO) object model is [InstanceSelection](#).

# IntermediateCubeDimensionID Element (ASSL)

Article • 12/09/2022

Contains the identifier (ID) of the dimension that relates a reference dimension to a measure group.

## Syntax

XML

```
<ReferenceMeasureGroupDimension>
 ...
 <IntermediateCubeDimensionID>...</IntermediateCubeDimensionID>
 ...
</ReferenceMeasureGroupDimension>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">ReferenceMeasureGroupDimension</a>
Child elements	None

## Remarks

The element that corresponds to the parent of `IntermediateCubeDimensionID` in the Analysis Management Objects (AMO) object model is [ReferenceMeasureGroupDimension](#).

## See Also

[Properties \(ASSL\)](#)

---

# IntermediateGranularityAttributeID Element (ASSL)

Article • 12/09/2022

Contains the identifier (ID) of the granularity attribute in the intermediate cube dimension that is used to relate a reference dimension to an intermediate dimension.

## Syntax

XML

```
<ReferenceMeasureGroupDimension>
 ...
 <IntermediateGranularityAttributeID>...
 </IntermediateGranularityAttributeID>
 ...
</ReferenceMeasureGroupDimension>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">ReferenceMeasureGroupDimension</a>
Child elements	None

## Remarks

The element that corresponds to the parent of `IntermediateGranularityAttributeID` in the Analysis Management Objects (AMO) object model is [ReferenceMeasureGroupDimension](#).

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# InvalidXmlCharacters Element (ASSL)

Article • 12/09/2022

Specifies the handling method for XML characters in the source data that are not valid.

## Syntax

XML

```
<DataItem>
 ...
 <InvalidXmlCharacters>...</InvalidXmlCharacters>
 ...
</DataItem>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Preserve</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataItem</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

Value	Description
<i>Preserve</i>	Invalid XML characters are preserved.
<i>Remove</i>	Invalid XML characters are removed.
<i>Replace</i>	Invalid XML characters are replaced with question mark (?) characters.

The enumeration that corresponds to the allowed values for `InvalidXmlCharacters` in the Analysis Management Objects (AMO) object model is [InvalidXmlCharacters](#).

# Invocation Element (ASSL)

Article • 12/09/2022

Specifies how an [Action](#) should be invoked.

## Syntax

XML

```
<Action>
 ...
 <Invocation>...</Invocation>
 ...
</Action>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Interactive</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Action</a>
Child elements	None

## Remarks

The invocation of an action depends on the client application. The **Invocation** element suggests to a client application how an action should be handled, and does not indicate to the instance of Analysis Services how to invoke an action.

The value of this element is limited to one of the strings in the following table.

 Expand table

Value	Description
<i>Interactive</i>	Invoked interactively by the user.
<i>OnOpen</i>	Invoked when a client application opens the object.
<i>Batch</i>	Invoked by a batch processing command.

The enumeration that corresponds to the allowed values for **Invocation** in the Analysis Management Objects (AMO) object model is [Action](#).

 No

# IsAggregatable Element (ASSL)

Article • 12/09/2022

Specifies whether the values of the [DimensionAttribute](#) element can be aggregated.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <IsAggregatable>...</IsAggregatable>
</DimensionAttribute>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **IsAggregatable** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# IsKey Element (ASSL)

Article • 12/09/2022

Indicates whether the column provides the key for the case in a [MiningStructure](#) element.

## Syntax

XML

```
<ScalarMiningStructureColumn>
 ...
 <IsKey>...</IsKey>
 ...
</ScalarMiningStructureColumn>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">ScalarMiningStructureColumn</a>
Child elements	None

## Remarks

One or more columns can be designated as key columns for each level of a nested table structure.

The element that corresponds to the parent of `IsKey` in the Analysis Management Objects (AMO) object model is [ScalarMiningStructureColumn](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

Yes

No

# Isolation Element (ASSL)

Article • 12/09/2022

Indicates the isolation level for an element that is derived from the [DataSource](#) data type.

## Syntax

XML

```
<DataSource>
 ...
 <Isolation>...</Isolation>
 ...
</DataSource>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ReadCommitted</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataSource</a>
Child elements	None

## Remarks

The value for this element is limited to one of the strings in the following table.

[Expand table](#)

Value	Description
<i>ReadCommitted</i>	Specifies that statements cannot read data that has been modified but not committed by other transactions. This prevents dirty reads. Other transactions can change data between individual statements within the current transaction. This results in nonrepeatable reads or phantom data. This value is the default for the <b>Isolation</b> element.
<i>Snapshot</i>	Specifies that the data that is read by any statement in a transaction will be the transactionally consistent version of the data that existed at the start of the transaction. The transaction can only see data modifications that were committed before the start of the transaction. Data modifications that are made by other transactions after the start of the current transaction are not visible to statements that are executing in the current transaction. The effect is as if the statements in a transaction get a snapshot of the committed data as it existed at the start of the transaction.

 Yes

 No

# KeyDuplicate Element (ASSL)

Article • 12/09/2022

Determines how Analysis Services handles a duplicate key error if it encounters one during processing.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyDuplicate>...</KeyDuplicate>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>IgnoreError</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

Duplicate key errors are generated only during dimension processing, when an attribute key is encountered more than once. Because attribute keys must be unique, Analysis Services discards the duplicate records. Duplicate key errors typically indicate a flaw in the design of the dimension, specifically in the relationships between attributes.

The value of this element is limited to one of the strings in the following table.

  [Expand table](#)

Value	Description
<i>IgnoreError</i>	Processing should ignore the error and continue.
<i>ReportAndContinue</i>	Processing should report the error and continue.
<i>ReportAndStop</i>	Processing should report the error and stop.

The enumeration that corresponds to the allowed values for **KeyDuplicate** in the Analysis Management Objects (AMO) object model is [ErrorOption](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# KeyErrorAction Element (ASSL)

Article • 12/09/2022

Specifies the action for Analysis Services to take when an error occurs on a key.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyErrorAction>...</KeyErrorAction>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ConvertToUnknown</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>ConvertToUnknown</i>	Convert the problem key to the unknown member value.
<i>DiscardRecord</i>	Discard the record.

The enumeration that corresponds to the allowed values for **KeyErrorAction** in the Analysis Management Objects (AMO) object model is [KeyErrorAction](#).

## See Also

[Properties \(ASSL\)](#)

# KeyErrorLimit Element (ASSL)

Article • 12/09/2022

Contains the number of acceptable errors during processing.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyErrorLimit>...</KeyErrorLimit>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Long
Default value	0
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **KeyErrorLimit** in the Analysis Management Objects (AMO) object model is [ErrorConfiguration](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

 Yes

 No

# KeyErrorLimitAction Element (ASSL)

Article • 12/09/2022

Specifies the action Analysis Services takes when the key error count that is specified in the [KeyErrorLimit](#) element is reached.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyErrorLimitAction>...</KeyErrorLimitAction>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>StopProcessing</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings in the following table.

[\[+\] Expand table](#)

Value	Description
<code>StopProcessing</code>	Stops processing the object.
<code>StopLogging</code>	Continues processing the object, but stops logging errors that are encountered during processing.

The enumeration that corresponds to the allowed values for **KeyErrorLimitAction** in the Analysis Management Objects (AMO) object model is [KeyErrorLimitAction](#).

## See Also

[Properties \(ASSL\)](#)

# KeyErrorLogFile Element (ASSL)

Article • 12/09/2022

Contains the file name for logging processing errors.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyErrorLogFile>...</KeyErrorLogFile>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **KeyLogFile** in the Analysis Management Objects (AMO) object model is [ErrorConfiguration](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# KeyNotFound Element (ASSL)

Article • 12/09/2022

Specifies how Analysis Services responds when it encounters a referential integrity error.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <KeyNotFound>...</KeyNotFound>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ReportAndContinue</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

Referential integrity errors occur when a foreign key value in a dependent table does not have a corresponding entry in the parent table. This error occurs when Analysis Services processes a dimension in which the fact table references a foreign key value that does not exist in the dimension table for that dimension, or when Analysis Services processes a partition when the dimension main table for a dimension that is included in the partition references a key value that does not exist in another associated dimension table. (In the case of dimensions with parent-child hierarchies and parent attributes, this can also occur when the dimension main table for a dimension that is included in the partition references a key value that does not exist in the same dimension table.)

The value of this element is limited to one of the strings in the following table.

[\[\] Expand table](#)

Value	Description
<i>IgnoreError</i>	Processing should ignore the error and continue.
<i>ReportAndContinue</i>	Processing should report the error and continue.
<i>ReportAndStop</i>	Processing should report the error and stop.

The enumeration that corresponds to the allowed values for **KeyNotFound** in the Analysis Management Objects (AMO) object model is [ErrorOption](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# KeyUniquenessGuarantee Element (ASSL)

Article • 12/09/2022

Indicates whether the relationship between the attribute key and its name, and the relationship to related attributes, is guaranteed to be valid.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <KeyUniquenessGuarantee>...</KeyUniquenessGuarantee>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

Analysis Services uses the **KeyUniquenessGuarantee** element to optimize query construction when it retrieves members from the underlying data source for this attribute.

The element that corresponds to the parent of **KeyUniquenessGuarantee** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# KpiID Element (ASSL)

Article • 12/09/2022

Contains an identifier (ID) that associates a [Kpi](#) element with a [Perspective](#) element.

## Syntax

XML

```
<PerspectiveKpi>
 ...
 <KpiID>...</KpiID>
 ...
</PerspectiveKpi>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">PerspectiveKpi</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **KpiID** in the Analysis Management Objects (AMO) object model is [PerspectiveKpi](#).

 No

# Language Element (ASSL)

Article • 12/09/2022

Contains the language identifier of the parent element.

## Syntax

XML

```
<Cube> <!-- or Database, Dimension, MiningModel, MiningStructure,
Translation -->
...
<Language>...</Language>
...
</Cube>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	None
Cardinality	See the table below.

[+] Expand table

Ancestor or Parent	Cardinality
Translation	1-1: Required element that occurs once and only once.
All others	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">Database</a> , <a href="#">Dimension</a> , <a href="#">MiningModel</a> , <a href="#">MiningStructure</a> , <a href="#">Translation</a>
Child elements	None

## Remarks

The **Language** element contains the default language identifier that is used by the parent element, or the specific language identifier for a **Translation** element. The language should be defined by using locale identifier (LCID) codes. For instance, LCID 1033 is used to indicate the English (U.S.) language.

The elements that correspond to the parents of the **Language** element in the Analysis Management Objects (AMO) object model are [Cube](#), [Database](#), [Dimension](#), [MiningModel](#), [MiningStructure](#), and [Translation](#).

## See Also

---

## Feedback

Was this page helpful?

 Yes

 No

# LastProcessed Element (ASSL)

Article • 12/09/2022

Contains the read-only timestamp that indicates when the database that contains the parent element was last processed.

## Syntax

XML

```
<Cube> <!-- or one of the elements listed in the Element Relationships table -->
...
<LastProcessed>...</LastProcessed>
...
</Cube>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	DateTime
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">Database</a> , <a href="#">Dimension</a> , <a href="#">MeasureGroup</a> , <a href="#">MiningModel</a> , <a href="#">MiningStructure</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

The instance of Analysis Services maintains the value of the **LastProcessed** element. The value changes only if the database that contains the parent element is processed.

Processing the parent element individually does not change the value of the **LastProcessed** element.

The elements that correspond to the parents of **LastProcessed** in the Analysis Management Objects (AMO) object model are [Cube](#), [Database](#), [Dimension](#), [MeasureGroup](#), [MiningModel](#), [MiningStructure](#), and [Partition](#).

# LastSchemaUpdate Element (ASSL)

Article • 12/09/2022

Contains the read-only metadata update timestamp of the parent element.

## Syntax

XML

```
<Assembly> <!-- or one of the elements that are listed in the Element
Relationships table -->
...
<LastSchemaUpdate>...</LastSchemaUpdate>
...
</Assembly>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	DateTime
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Assembly</a> , <a href="#">Cube</a> , <a href="#">Database</a> , <a href="#">DataSource</a> , <a href="#">DataSourceView</a> , <a href="#">Dimension</a> , <a href="#">MdxScript</a> , <a href="#">MeasureGroup</a> , <a href="#">MiningModel</a> , <a href="#">MiningStructure</a> , <a href="#">Partition</a> , <a href="#">Permission</a> , <a href="#">Perspective</a>
Child elements	None

## Remarks

The **LastSchemaUpdate** element contains a read-only **DateTime** value that represents the date and time that the metadata for an object was changed on a given instance of Analysis Services.

The elements that correspond to the parents of **LastSchemaUpdate** in the Analysis Management Objects (AMO) object model are [Assembly](#), [Cube](#), [Database](#), [DataSource](#), [DataSourceView](#), [Dimension](#), [MdxScript](#), [MeasureGroup](#), [MiningModel](#), [MiningStructure](#), [Partition](#), [Permission](#), and [Perspective](#).

 ...
</Trace>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Trace</a>
Child elements	None

## Remarks

The log file is saved to the Log folder of the instance of Analysis Services.

The element that corresponds to the parent of **LogFileName** in the Analysis Management Objects (AMO) object model is [Trace](#).

## See Also

# LogFileRollover Element (ASSL)

Article • 12/09/2022

Specifies whether logging of [Trace](#) output should roll over to a new file or should stop when the maximum log file size that is specified in [LogFileSize](#) is reached.

## Syntax

XML

```
<Trace>
 ...
 <LogFileRollover>...</LogFileRollover>
 ...
</Trace>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	Boolean
Default value	False
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Trace</a>
Child elements	None

## Remarks

If the value of the **LogFileRollover** element is set to True, a new file is started when the size of the log file exceeds the value that is specified in the **LogFileSize** element of the **Trace** parent element; otherwise, logging stops.

The element that corresponds to the parent of **LogFileRollover** in the Analysis Management Objects (AMO) object model is [Trace](#).

# LogFileSize Element (ASSL)

Article • 12/09/2022

Specifies the maximum log file size, in megabytes.

## Syntax

XML

```
<Trace>
 <LogFileSize>...</LogFileSize>
</Trace>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	5 (megabytes)
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Trace</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **LogFileSize** in the Analysis Management Objects (AMO) object model is [Trace](#).

# ManagedProvider Element (ASSL)

Article • 12/09/2022

Contains the name of the managed provider used by an element that is derived from the [DataSource](#) data type.

## Syntax

XML

```
<DataSource>
 ...
 <ManagedProvider>...</ManagedProvider>
 ...
</DataSource>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataSource</a>
Child elements	None

## Remarks

If a data source uses a managed provider, the **ManagedProvider** element contains the name of the managed provider.

# ManufacturingExtraMonthQuarterElement (ASSL)

Article • 12/09/2022

Defines the month of the manufacturing period to which an extra month is assigned for a [TimeBinding](#) element.

## Syntax

XML

```
<TimeBinding>
 ...
 <ManufacturingExtraMonthQuarter>...</ManufacturingExtraMonthQuarter>
 ...
</TimeBinding>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	Integer (1 through 4)
Default value	4
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">TimeBinding</a>

# MasterDatasourceID Element (ASSL)

Article • 12/09/2022

Contains the master data source identifier (ID) for a [Database](#) element.

## Syntax

XML

```
<Database>
 ...
 <MasterDatasourceID>...</MasterDatasourceID>
 ...
</Database>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">Database</a>
Child elements	None

## Remarks

For databases on remote instances of Analysis Services that contain remote partitions, the **MasterDataSourceID** element contains the data source ID of the data source used to identify the master instance of Analysis Services that manages the remote partitions.

The element that corresponds to the parent of **MasterDataSourceID** in the Analysis Management Objects (AMO) object model is [Database](#).

# Materialization Element (ASSL)

Article • 12/09/2022

Indicates the type of relationship between the measure group and the reference dimension.

## Syntax

XML

```
<ReferenceMeasureGroupDimension>
 ...
 <Materialization>...</Materialization>
 ...
</ReferenceMeasureGroupDimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Indirect</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ReferenceMeasureGroupDimension</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>Regular</i>	The reference dimension has a regular relationship, as with regular dimensions.
<i>Indirect</i>	The reference dimension has an indirect relationship, such as with many-to-many dimensions.

The element that corresponds to the parent of **Materialization** in the Analysis Management Objects (AMO) object model is [ReferenceMeasureGroupDimension](#).

# MaxActiveConnections Element (ASSL)

Article • 12/09/2022

Contains the maximum number of concurrent connections allowed by an element that is derived from the [DataSource](#) data type.

## Syntax

XML

```
<DataSource>
 ...
 <MaxActiveConnections>...</MaxActiveConnections>
 ...
</DataSource>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	10
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataSource</a>
Child elements	None

## Remarks

If the value of this element is set to zero, the maximum number of concurrent connections is determined by the data cartridge that is used to access the data source. If the value of this element is set to a negative value, the maximum number of concurrent connections is unlimited.

# MeasureQualification Element (ASSL)

Article • 12/09/2022

Determines whether a prefix is applied to measures in the [MeasureGroup](#).

## Syntax

XML

```
<MeasureGroup>
 ...
 <MeasureQualification>...</MeasureQualification>
 ...
</MeasureGroup>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MeasureGroup</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>None</i>	No prefix is applied to measures within this measure group.
<i>PrefixMeasureGroup</i>	The unique name and caption of each measure in this measure group is prefixed by the name of the measure group and a single space.

The element that corresponds to the parent of **MeasureQualification** in the Analysis Management Objects (AMO) object model is [MeasureGroup](#).

XML

```
<Action> <!-- or one of the elements listed below in the Element
Relationships table -->
...
<Name>...</Name>
...
</Action>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (up to 100 characters)
Default value	Varies
Cardinality	1-1: Required element that occurs once and only once

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	Action, Aggregation, AggregationDesign, AlgorithmParameter, Annotation, Assembly, ClrAssemblyFile, Cube, CubeDimension, CubeHierarchy, Database, DataSource, DataSourceView, Dimension, DimensionAttribute, Group, Hierarchy, Kpi, Level, MdxScript, Measure, MeasureGroup, MemberProperty, MiningModel, MiningModelColumn, MiningStructure, MiningStructureColumn, Partition, Permission, Perspective, PerspectiveCalculation, ReportFormatParameter, ReportParameter, Role, Server, ServerProperty, Trace

<b>Relationship</b>	<b>Element</b>
Child elements	None

## Remarks

Every element that is used to define an object (an instance of Analysis Services, a hierarchy, an attribute, and so on) has a **Name** element as a property. The value of a **Name** element has the following restrictions:

- The value cannot contain leading or trailing spaces. If leading or trailing spaces are included in the value of a **Name** element, those spaces will be implicitly removed by Analysis Services.
- The value should not contain control characters. The presence of control characters in a name is strongly discouraged and can sometimes result in XML validation errors.

For objects created using the **GetNewName** method in SQL Server, AMO checks for and subsequently removes any control characters, leading spaces, or trailing spaces in the name. For this reason, using **GetNewName** is the recommended approach for setting object names.

However, if you set the **Name** property directly, the same validation checks are not performed, possibly resulting in XML validation errors. Whether an error actually occurs depends on which control character appears in the name.

Although control characters should never be used in an object name, Analysis Services does not expressly prevent them. Previous releases of Analysis Services sometimes accepted control characters in an object name. For this reason, SQL Server 2016 Analysis Services and later will ignore control characters in an object name to avoid breaking older solutions.

- The following reserved values cannot be used:
  - AUX
  - CLOCK\$
  - COM1 through COM9 (COM1, COM2, COM3, and so on)
  - CON

- LPT1 through LPT9 (LPT1, LPT2, LPT3, and so on)
- NUL
- PRN

The following table lists additional characters that cannot be used within the value of a **Name** element, depending on the parent element.

[\[+\] Expand table](#)

Parent element	Invalid Characters
Server	The name must follow the rules for Windows computer names. IP addresses are not valid.
DataSource	:/\*\&#124;?"()[]{}<>`
Level, Attribute Element	. , ; ' : /\*\&#124;?"&%\$!+=[]{}<>`
All other parent elements	. , ; ' : /\*\&#124;?"&%\$!+=()[]{}<>`

# NamingTemplate Element (ASSL)

Article • 12/09/2022

Defines how levels are named in a parent-child hierarchy constructed from the [DimensionAttribute](#) parent element.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <NamingTemplate>...</NamingTemplate>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The value of the **NamingTemplate** element is used only by parent attributes (in other words, the value of the [Usage](#) element of the **DimensionAttribute** parent element is set to *Parent*).

When a parent attribute is used to construct a hierarchy, the levels of the hierarchy are determined by the parent-child relationships between members contained by the parent attribute. Therefore, unlike other dimensions, the level names cannot be drawn from the attribute names used for the hierarchy.

Instead, a naming template is used to generate level names for parent-child hierarchies. The **NamingTemplate** element, defined in the parent attribute, contains a string expression used to define level names. There are two ways to define a naming template for a parent attribute. You can either design a naming pattern, or you can specify a list of names.

A naming pattern contains an asterisk (\*) as a placeholder character for a counter that is incremented and inserted into the name of each new and deeper level. For example, using `Level *` results in the level names `Level 01`, `Level 02`, `Level 03`, and so on, if no (All) level is defined. If a naming pattern does not contain the placeholder character, it is first used as is, and then subsequent level names are formed by appending a space and a number to the end of the pattern. For example, using `Level` results in the level names `Level`, `Level 01`, `Level 02`, and so on.

To use a specific set of names for the naming, the value of the **NamingTemplate** element is set to a semicolon-delimited list of level names. Each name in the list is used for a subsequent level name. If the number of levels exceeds the number of names in the list, the last name in the list is used as a template for any additional level names, with a space and ordinal number appended to the last name as described earlier. For example, using `Division;Group;Unit` results in the level names `Division`, `Group`, `Unit`, `Unit 01`, `Unit 02`, and so on. By contrast, using `Division;Group;Unit *` results in the level names `Division`, `Group`, `Unit 03`, `Unit 04`, and so on.

Each name in the list is treated as a template to ensure uniqueness of level names. For example, using `Manager;Team Lead;Manager;Team Lead;Worker *` results in the level names `Manager`, `Team Lead`, `Manager 01`, `Team Lead 01`, `Worker 05`, `Worker 06`.

Use two asterisks (\*\*) to include the asterisk (\*) character in a level name as part of a naming template.

The element that corresponds to the parent of **NamingTemplate** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# NotificationTechnique Element (ASSL)

Article • 12/09/2022

Specifies whether or an external client application processes the notifications.

## Syntax

XML

```
<ProactiveCachingBinding>
 <NotificationTechnique>...</NotificationTechnique>
</ProactiveCachingBinding>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Client</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">ProactiveCachingBinding</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Client</i>	External client application processes the notification.
<i>Server</i>	Processes the notification.

The element that corresponds to the parent of **NotificationTechnique** in the Analysis Management Objects (AMO) object model is [ProactiveCachingBinding](#).

The enumeration that corresponds to the allowed values for **NotificationTechnique** in the Analysis Management Objects (AMO) object model is [NotificationTechnique](#).

# NullKeyConvertedToUnknown Element (ASSL)

Article • 12/09/2022

Specifies the action to be taken when a null conversion error is encountered.

## Syntax

XML
<pre>&lt;ErrorConfiguration&gt;   ...     &lt;NullKeyConvertedToUnknown&gt;...&lt;/NullKeyConvertedToUnknown&gt;   ... &lt;/ErrorConfiguration&gt;</pre>

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>IgnoreError</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

Null conversion errors occur when a null value is encountered in a key column and interpreted as the **Unknown** member. However, this error occurs only if the **NullProcessing** element for the **DataItem** ancestor of the **ErrorConfiguration** parent element is set to *UnknownMember*.

The value of this element is limited to one of the strings listed in the following table.

  [Expand table](#)

Value	Description
<i>IgnoreError</i>	Processing ignores the error and continues.
<i>ReportAndContinue</i>	Processing reports the error and continues.
<i>ReportAndStop</i>	Processing reports the error and stops.

The enumeration that corresponds to the allowed values for **NullKeyConvertedToUnknown** in the Analysis Management Objects (AMO) object model is [ErrorOption](#).

## See Also

 Yes

 No

# NullKeyNotAllowed Element (ASSL)

Article • 12/09/2022

Determines how the Analysis Services processing engine handles a null key error encountered during processing.

## Syntax

XML

```
<ErrorConfiguration>
 ...
 <NullKeyNotAllowed>...</NullKeyNotAllowed>
 ...
</ErrorConfiguration>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ReportAndContinue</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ErrorConfiguration</a>
Child elements	None

## Remarks

Null key errors occur when a null value is encountered in a key column in which null values are not allowed, forcing the record to be discarded during processing. However, this error occurs only if the [NullProcessing](#) element for the **DataItem** ancestor of the **ErrorConfiguration** parent element is set to *Error*.

The value of this element is limited to one of the strings in the following table.

[\[+\] Expand table](#)

Value	Description
<i>IgnoreError</i>	Processing ignores the error and continues.
<i>ReportAndContinue</i>	Processing reports the error and continues.
<i>ReportAndStop</i>	Processing reports the error and stops.

The enumeration that corresponds to the allowed values for **NullKeyNotAllowed** in the Analysis Management Objects (AMO) object model is [ErrorOption](#).

# NullProcessing Element (ASSL)

Article • 12/09/2022

Defines how null values are processed.

## Syntax

XML

```
<DataItem>
 ...
 <NullProcessing>...</NullProcessing>
 ...
</DataItem>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Automatic</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataItem</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Preserve</i>	<p>Preserves the null value.</p> <p>Note: This value is not supported for distinct count measures.</p>
<i>Error</i>	<p>Raises a null key error. The value of <a href="#">NullKeyNotAllowed</a> determines how the instance reacts to the error.</p> <p>Note: This value is not supported for measures.</p>
<i>UnknownMember</i>	<p>Generates an unknown member and raises a null conversion error. The value of <a href="#">NullKeyConvertedToUnknown</a> determines how the instance reacts to the error.</p> <p>Note: This value is not supported for columns associated with measures.</p>
<i>ZeroOrBlank</i>	<p>Converts the null value to zero (for numeric data items) or a blank string (for string data items).</p> <p>Note: This value provides compatibility with previous versions of Analysis Services.</p>
<i>Automatic</i>	<p>Uses the default processing appropriate for the element:</p> <ul style="list-style-type: none"> <li><i>ZeroOrBlank</i> for OLAP data items.</li> <li><i>UnknownMember</i> for data mining data items.</li> </ul>

The enumeration that corresponds to the allowed values for `NullProcessing` in the Analysis Management Objects (AMO) object model is [NullProcessing](#).

# OnlineMode Element (ASSL)

Article • 12/09/2022

Specifies whether the database is brought back online immediately when the rebuilding of the cache is initiated, or only when the rebuilding of the cache is complete.

## Syntax

XML

```
<ProactiveCaching>
 ...
 <OnlineMode>...</OnlineMode>
 ...
</ProactiveCaching>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Immediate</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ProactiveCaching</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[\] Expand table](#)

Value	Description
<i>Immediate</i>	Database is brought back online immediately when the rebuilding of the cache is initiated.
<i>OnCacheComplete</i>	Database is brought back online only when the rebuilding of the cache is complete.

The enumeration that corresponds to the allowed values for **OnlineMode** in the Analysis Management Objects (AMO) object model is [ProactiveCaching](#).

# OptimizedState Element (ASSL)

Article • 12/09/2022

Determines the level of optimization that is applied to the hierarchy.

## Syntax

XML

```
<CubeHierarchy>
 ...
 <OptimizedState>...</OptimizedState>
 ...
</CubeHierarchy>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>FullyOptimized</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">CubeHierarchy</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>FullyOptimized</i>	The instance builds indexes for the hierarchy to improve query performance.
<i>NotOptimized</i>	The instance does not build additional indexes.

The enumeration that corresponds to the allowed values for **OptimizedState** in the Analysis Management Objects (AMO) object model is [OptimizationType](#).

# Optionality Element (ASSL)

Article • 12/09/2022

Indicates the optionality of the members for an [AttributeRelationship](#) element.

## Syntax

XML

```
<AttributeRelationship>
 ...
 <Optionality>...</Optionality>
 ...
</AttributeRelationship>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Mandatory</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">AttributeRelationship</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Mandatory</i>	Each member in the related attribute has to be associated with at least one member in the attribute that owns the <b>AttributeRelationship</b> element.
<i>Optional</i>	Each member in the related attribute does not have to be associated with at least one member in the attribute that owns the <b>AttributeRelationship</b> element.

The enumeration that corresponds to the allowed values for **Cardinality** in the Analysis Management Objects (AMO) object model is [Optionality](#).

# OrderBy Element (ASSL)

Article • 12/09/2022

Describes how to order the members contained in the attribute.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <OrderBy>...</OrderBy>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Name</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Name</i>	Order by the member name.
<i>Key</i>	Order by the member key.
<i>AttributeKey</i>	Order by the member key of the attribute specified in the <a href="#">OrderByAttributeID</a> element of <b>DimensionAttribute</b> .
<i>AttributeName</i>	Order by the member name of the attribute specified in the <a href="#">OrderByAttributeID</a> element of <b>DimensionAttribute</b> .

The enumeration that corresponds to the allowed values for **OrderBy** in the Analysis Management Objects (AMO) object model is [OrderBy](#).

## See Also

 Yes

 No

# OrderByAttributeID Element (ASSL)

Article • 12/09/2022

Identifies another attribute by which to order the members of the [Dimension](#) attribute.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <OrderByAttributeID>...</OrderByAttributeID>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The **OrderByAttributeID** element is only used when the value of the [OrderBy](#) element for the **DimensionAttribute** is set to *AttributeKey* or *AttributeName*.

The element that corresponds to the parent of **OrderByAttributeID** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

 No

# Ordinal Element (ASSL)

Article • 12/09/2022

Indicates the ordinal number to bind to in collections such as keys and translations.

## Syntax

XML

```
<AttributeBinding> <!-- or CubeAttributeBinding -->
...
<Ordinal>...</Ordinal>
...
</AttributeBinding>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	0
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">AttributeBinding</a> , <a href="#">CubeAttributeBinding</a>
Child elements	None

## Remarks

**AttributeBinding** and **CubeAttributeBinding** elements in which the **Type** property is set to either *Key* or *Translation* can be bound to an attribute that is in turn bound to a collection of columns in the data source view. The value of the **Ordinal** element determines to which column the **AttributeBinding** or **CubeAttributeBinding** refers in that collection.

The elements that correspond to the parents of **Ordinal** in the Analysis Management Objects (AMO) object model are [AttributeBinding](#) and [CubeAttributeBinding](#).

# OverrideBehavior Element (ASSL)

Article • 12/09/2022

Indicates the override behavior of the relationship described by an [AttributeRelationship](#) element.

## Syntax

XML

```
<AttributeRelationship>
 ...
 <OverrideBehavior>...</OverrideBehavior>
 ...
</AttributeRelationship>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Strong</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">AttributeRelationship</a>
Child elements	None

## Remarks

The **OverrideBehavior** element determines how positioning on the related attribute affects the positioning on the attribute

The value of this element is limited to one of the strings listed in the following table.

 Expand table

Value	Description
<i>Strong</i>	Indicates the override behavior of the relationship described by an AttributeRelationship element. Dictates how positioning on one attribute affects the position of the other.
<i>None</i>	No effect.

The enumeration that corresponds to the allowed values for **OverrideBehavior** in the Analysis Management Objects (AMO) object model is [OverrideBehavior](#).

---

 No

# PartitionID Element (ASSL)

Article • 12/09/2022

Associates a [Partition](#) element with a parent element, binding, or out-of-line binding.

## Syntax

XML

```
<PartitionBinding>
 ...
 <PartitionID>...</PartitionID>
 ...
</PartitionBinding>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">PartitionBinding</a>
Child elements	None

## Remarks

# Feedback

Was this page helpful?

 Yes

 No

# Password Element (ASSL)

Article • 12/09/2022

Contains the password of the user account for the [ImpersonationInfo](#) element.

## Syntax

XML

```
<ImpersonationInfo
...
 <Password>...</Password>
...
</ImpersonationInfo>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ImpersonationInfo</a>
Child elements	None

## Remarks

The value of the **Password** element, as well as the value of the **Account** element, is used for impersonation purposes if the value of the **ImpersonationMode** element for any element derived from the **ImpersonationInfo** data type is set to *ImpersonateAccount*.

Only members of the server administrator role for the Analysis Services instance can provide a blank value for the **Password** element

## Feedback

Was this page helpful?

 Yes

 No

# Path Element (ASSL)

Article • 12/09/2022

Contains the path, as provided by an instance of Reporting Services, of a report used by the [ReportAction](#) element.

## Syntax

XML

```
<ReportAction>
 ...
 <Path>...</Path>
 ...
</ReportAction>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that occurs once and only once

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ReportAction</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **Path** in the Analysis Management Objects (AMO) object model is [ReportAction](#).

 No

# PendingValue Element (ASSL)

Article • 12/09/2022

Contains the read-only pending value of the associated [ServerProperty](#) element.

## Syntax

XML

```
<ServerProperty>
 ...
 <PendingValue>...</PendingValue>
 ...
</ServerProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Any simpleType
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ServerProperty</a>
Child elements	None

## Remarks

This element contains the value of the **ServerProperty** that will be used the next time the current instance of Analysis Services is started. This value is typically retrieved from wherever the value for the server property is stored—in an initialization file, the Windows registry, or another storage mechanism.

The element that corresponds to the parent of **PendingValue** in the Analysis Management Objects (AMO) object model is [ServerProperty](#).

# PermissionSet Element (ASSL)

Article • 12/09/2022

Identifies the permission set associated with a .NET Framework assembly.

## Syntax

XML

```
<ClrAssembly>
 ...
 <PermissionSet>...</PermissionSet>
</ClrAssembly>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Safe</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ClrAssembly</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Safe</i>	Only internal computation and local data access is allowed. <i>Safe</i> is the most restrictive permission set. Code executed by an assembly with <i>Safe</i> permissions cannot access external system resources such as files, the network, environment variables, or the registry.
<i>ExternalAccess</i>	<i>Safe</i> , with the additional ability to access external system resources such as files, networks, environmental variables, and the registry.
<i>Unrestricted</i>	Unrestricted allows assemblies unrestricted access to resources, both within and outside . Code executing from within an <i>Unrestricted</i> assembly can call unmanaged code.

The enumeration that corresponds to the allowed values for **PermissionSet** in the Analysis Management Objects (AMO) object model is [PermissionSet](#).

# Persistence Element (ASSL)

Article • 12/09/2022

Determines which parts of the bound source data are dynamic and are checked for updates using the frequency specified by the [RefreshPolicy](#) element.

## Syntax

XML

```
<DimensionBinding> <!-- or MeasureGroupBinding -->
...
<Persistence>...</Persistence>
...
</DimensionBinding>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>NotPersisted</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">DimensionBinding</a> , <a href="#">MeasureGroupBinding</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>NotPersisted</i>	Source metadata, members, and data are all dynamic.
<i>MetaData</i>	Source metadata is static, but members and data are dynamic.
<i>All</i>	Source metadata, members, and data are all static.

The enumeration that corresponds to the allowed values for **Persistence** in the Analysis Management Objects (AMO) object model is [PersistenceType](#).

# ProcessingMode Element (ASSL)

Article • 12/09/2022

Indicates whether the instance should index and aggregate during or after processing.

## Syntax

XML

```
<Cube> <!-- or Dimension, MeasureGroup, Partition -->
...
<ProcessingMode>...</ProcessingMode>
...
</Cube>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">Dimension</a> , <a href="#">MeasureGroup</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

The value of **ProcessingMode** on the **Cube** provides the default for the cube, and can be overridden by setting **ProcessingMode** for each partition.

The value of this element is limited to one of the strings listed in the following table.

 Expand table

Value	Description
<i>Regular</i>	The instance indexes and performs aggregations during processing.
<i>LazyOptimizations</i>	The instance indexes and performs aggregations after processing.

The enumeration that corresponds to the allowed values for **ProcessingMode** in the Analysis Management Objects (AMO) object model is [ProcessingMode](#).

# Read Element (ASSL)

Article • 12/09/2022

Determines whether data or metadata can be read for a given [CubeDimensionPermission](#) or [Permission](#) element.

## Syntax

XML

```
<CubeDimensionPermission> <!-- or Permission -->
...
<Read>...</Read>
...
</CubeDimensionPermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">CubeDimensionPermission</a> , <a href="#">Permission</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>None</i>	No access is permitted to data or metadata from the parent object.
<i>Allowed</i>	Read access is permitted to data and metadata from the parent object.

The elements that correspond to the parents of **Read** in the Analysis Management Objects (AMO) object model are [CubeDimensionPermission](#) and [Permission](#).

# ReadDefinition Element (ASSL)

Article • 12/09/2022

Determines whether members can read the definition of the database or the definition of objects in the database.

## Syntax

XML

```
<Permission> <!-- or one of the elements listed below in the Element
Relationships table -->
...
 <ReadDefinition>...</ReadDefinition>
...
</Permission>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CubePermission</a> , <a href="#">DatabasePermission</a> , <a href="#">DimensionPermission</a> , <a href="#">MiningModelPermission</a> , <a href="#">MiningStructurePermission</a> , <a href="#">Permission</a>
Child elements	None

# Remarks

The value of this element is limited to one of the strings listed in the following table.

[+] Expand table

Value	Description
<i>None</i>	Access to the object definition is not allowed.
<i>Basic</i>	Basic access to the object definition is allowed.  Note: This permission is required for creating local cubes, linking measure groups, and linking dimensions.
<i>Allowed</i>	Full access to the object definition is allowed.  Note: This permission is required for executing a <a href="#">Discover</a> XML for Analysis (XMLA) call using the DISCOVER_XML_METADATA parameter.

The elements that correspond to the parents of **ReadDefinition** in the Analysis Management Objects (AMO) object model are [CubePermission](#), [DatabasePermission](#), [DimensionPermission](#), [MiningModelPermission](#), [MiningStructurePermission](#), and [Permission](#).

# ReadSourceData Element (ASSL)

Article • 12/09/2022

Determines how unique names are generated for hierarchies that are contained within the [CubePermission](#).

## Syntax

XML

```
<CubePermission>
 ...
 <ReadSourceData>...</ReadSourceData>
 ...
</CubePermission>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">CubePermission</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[] [Expand table](#)

Value	Description
<i>None</i>	No access is permitted to data available on calculation pass 0.
<i>Allowed</i>	Access is permitted to data available on calculation pass 0.

The element that corresponds to the parent of **ReadSourceData** in the Analysis Management Objects (AMO) object model is [CubePermission](#).

# RefreshInterval Element (ASSL)

Article • 12/09/2022

Specifies the interval at which the bound data associated with the parent element is refreshed.

## Syntax

XML

```
<DimensionBinding> <!-- or MeasureGroupBinding,
ProactiveCachingIncrementalProcessingBinding, ProactiveCachingQueryBinding -
-->
...
 <RefreshInterval>...</RefreshInterval>
...
</DimensionBinding>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	XML duration
Default value	When the Ancestor or Parent is <a href="#">ProactiveCachingIncrementalProcessingBinding</a> or <a href="#">ProactiveCachingQueryBinding</a> , the default value is PT-1s. In all other cases, it is PT1m.
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">DimensionBinding</a> , <a href="#">MeasureGroupBinding</a> , <a href="#">ProactiveCachingIncrementalProcessingBinding</a> , <a href="#">ProactiveCachingQueryBinding</a>

Relationship	Element
Child elements	None

## Remarks

The elements that correspond to the parents of **RefreshInterval** in the Analysis Management Objects (AMO) object model are [DimensionBinding](#), [MeasureGroupBinding](#), [ProactiveCachingIncrementalProcessingBinding](#), and [ProactiveCachingQueryBinding](#).

# RefreshPolicy Element (ASSL)

Article • 12/09/2022

Determines how often the dynamic part of the dimension or measure group (as specified by the [Persistence element](#)) is checked for changes.

## Syntax

XML

```
<DimensionBinding> <!-- or MeasureGroupBinding -->
...
<RefreshPolicy>...</RefreshPolicy>
...
</DimensionBinding>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	See the table below.
Cardinality	0-1: Optional element that can occur once and only once.

[\[+\] Expand table](#)

Ancestor or Parent	Default Value
DimensionBinding	<i>ByQuery</i>
MeasureGroupBinding	None

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">DimensionBinding</a> , <a href="#">MeasureGroupBinding</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>ByQuery</i>	Every query checks to see whether the source data has changed.
<i>ByInterval</i>	Source data is only checked for changes at the interval specified by <a href="#">RefreshInterval</a> .

The enumeration that corresponds to the allowed values for **RefreshPolicy** in the Analysis Management Objects (AMO) object model is [RefreshPolicy](#).

# RelationshipType Element (ASSL)

Article • 12/09/2022

Indicates whether member relationships for an [AttributeRelationship](#) can be changed.

## Syntax

XML

```
<AttributeRelationship>
 ...
 <RelationshipType>...</RelationshipType>
 ...
</AttributeRelationship>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Flexible</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">AttributeRelationship</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Rigid</i>	The member relationships between an attribute and a related attribute cannot be changed.
<i>Flexible</i>	The member relationships between an attribute and a related attribute can be changed.

For example, if **ZipCode** cannot change from one **City** to another, the relationship from **ZipCode** to **City** is marked as *Rigid*.

The enumeration that corresponds to the allowed values for **RelationshipType** in the Analysis Management Objects (AMO) object model is [RelationshipType](#).

# RemoteDatasourceID Element (ASSL)

Article • 12/09/2022

Specifies the identifier (ID) of the OLAP data source that points to the instance of Analysis Services that stores the remote partition.

## Syntax

XML

```
<Partition>
 ...
 <RemoteDatasourceID>...</RemoteDatasourceID>
 ...
</Partition>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Partition</a>
Child elements	None

## Remarks

If **RemoteDatasourceID** is null, then the partition is local.

The element that corresponds to the parent of **RemoteDatasourceID** in the Analysis Management Objects (AMO) object model is [Partition](#).

# ReportingFirstMonth Element (ASSL)

Article • 12/09/2022

Defines the first reporting month for the [TimeBinding](#) element.

## Syntax

XML

```
<TimeBinding>
 ...
 <ReportingFirstMonth>...</ReportingFirstMonth>
 ...
</TimeBinding>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	Integer (1 through 12, where 1=January and 12=December)
Default value	1
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">TimeBinding</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **ReportingFirstMonth** in the Analysis Management Objects (AMO) object model is [TimeBinding](#).

# ReportingWeekToMonthPattern Element (ASSL)

Article • 12/09/2022

Defines the reporting week-to-month pattern for the [TimeBinding](#) element.

## Syntax

```
XML

<TimeBinding>
 ...
 <ReportingWeekToMonthPattern>...</ReportingWeekToMonthPattern>
 ...
</TimeBinding>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	445
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">TimeBinding</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[\] Expand table](#)

Value	Description
445	4 weeks in the first month of the quarter, 4 weeks in the second month, and 5 weeks in the third month.
454	4 weeks in the first month of the quarter, 5 weeks in the second month, and 4 weeks in the third month.
544	5 weeks in the first month of the quarter, 4 weeks in the second month, and 4 weeks in the third month.

The enumeration that corresponds to the allowed values for **ReportingWeekToMonthPattern** in the Analysis Management Objects (AMO) object model is [ReportingWeekToMonthPattern](#).

# RequiresRestart Element (ASSL)

Article • 12/09/2022

Contains a read-only value associated with a [ServerProperty](#) element that determines whether changing the value of the server property requires that the instance be restarted for the change to take effect.

## Syntax

XML

```
<ServerProperty>
 ...
 <RequiresRestart>...</RequiresRestart>
 ...
</ServerProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ServerProperty</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **RequiresRestart** in the Analysis Management Objects (AMO) object model is [ServerProperty](#).

# Root Element (ASSL)

Article • 12/09/2022

Contains the data (rowset) for a data source.

## Syntax

XML

```
<PushedDataSource>
 ...
 <Root>...</Root>
 ...
</PushedDataSource>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Rowset
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">PushedDataSource</a>
Child elements	None

## See Also

[Properties \(ASSL\)](#)

---

# Feedback

Was this page helpful?

 Yes

 No

# RootMemberIf Element (ASSL)

Article • 12/09/2022

Determines how the root member or members of a parent attribute are identified.

## Syntax

XML

```
<DimensionAttribute>
 ...
 <RootMemberIf>...</RootMemberIf>
 ...
</DimensionAttribute>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>ParentIsBlankSelfOrMissing</i>
Cardinality	0-1: Optional element that can occur once and only once

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DimensionAttribute</a>
Child elements	None

## Remarks

The value of the **RootMemberIf** element is used only by parent attributes (in other words, the value of the [Usage](#) element of the **DimensionAttribute** parent element is set to *Parent*) to determine the root (topmost) members of a parent-child hierarchy.

The value of this element is limited to one of the strings listed in the following table.

  [Expand table](#)

Value	Description
<i>ParentIsBlankSelfOrMissing</i>	Only members that meet one or more of the conditions described for <i>ParentIsBlank</i> , <i>ParentIsSelf</i> , or <i>ParentIsMissing</i> are treated as root members.
<i>ParentIsBlank</i>	Only members with a null, a zero, or an empty string in the key columns represented by the <a href="#">KeyColumns</a> collection of <b>DimensionAttribute</b> are treated as root members.
<i>ParentIsSelf</i>	Only members with themselves as parents are treated as root members.
<i>ParentIsMissing</i>	Only members with parents that cannot be found are treated as root members.

The enumeration that corresponds to the allowed values for **RootMemberIf** in the Analysis Management Objects (AMO) object model is [RootIfValue](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# Schema Element (ASSL)

Article • 12/09/2022

Contains the schema of the data source view.

## Syntax

XML

```
<DataSourceView>
 ...
 <Schema>...</Schema>
 ...
</DataSourceView>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Schema
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	DataSourceView
Child elements	None

## Remarks

The **Schema** is represented using the XML Schema Definition (XSD) language format of DataSets in the .NET Framework, with some extensions for DataSets and others specific to this usage within the data definition language (DDL). DataSets define a flexible mapping from XSD to a relational schema, but then return XSD in a more canonical form. Only this canonical form is valid within data sources.

The element that corresponds to the parent of **Schema** in the Analysis Management Objects (AMO) object model is [DataSourceView](#).

## See Also

 No

# ScriptCacheProcessingMode Element (ASSL)

Article • 12/09/2022

Indicates whether the server should build the script cache during processing or after processing.

## Syntax

XML

```
<Cube>
 ...
 <ScriptCacheProcessingMode>...</ScriptCacheProcessingMode>
 ...
</Cube>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Cube</a>
Child elements	None

# Remarks

The value of this element is limited to one of the strings in the following table.

[+] Expand table

Value	Description
<i>Regular</i>	The server builds the script cache during processing.
<i>Lazy</i>	The server builds the script cache after processing.

The enumeration that corresponds to the allowed values for **ScriptCacheProcessingMode** in the Analysis Management Objects (AMO) object model is [ScriptCacheProcessingMode](#).

The element that corresponds to the parent of **ScriptCacheProcessingMode** in the Analysis Management Objects (AMO) object model is [Cube](#).

# SilenceInterval Element (ASSL)

Article • 12/09/2022

Defines the minimum amount of time the instance of Analysis Services pauses before starting the multidimensional OLAP (MOLAP) imaging process.

## Syntax

XML

```
<ProactiveCaching>
 ...
 <SilenceInterval>...</SilenceInterval>
 ...
</ProactiveCaching>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	duration
Default value	P0s
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ProactiveCaching</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **SilenceInterval** in the Analysis Management Objects (AMO) object model is [ProactiveCaching](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

Was this page helpful?

 Yes

 No

# SilenceOverrideInterval Element (ASSL)

Article • 12/09/2022

Defines the amount of time that must elapse after receiving initial notification before multidimensional OLAP (MOLAP) imaging begins unconditionally.

## Syntax

XML

```
<ProactiveCaching>
 ...
 <SilenceOverrideInterval>...</SilenceOverrideInterval>
 ...
</ProactiveCaching>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	duration
Default value	P0s
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">ProactiveCaching</a>
Child elements	None

## Remarks

The value of **SilenceOverrideInterval** overrides the value of **SilenceInterval** if a notification is received during the silence period.

The element that corresponds to the parent of **SilenceOverrideInterval** in the Analysis Management Objects (AMO) object model is [ProactiveCaching](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

 No

# Slice Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression defining the slice contained in a partition.

## Syntax

XML

```
<Partition>
 ...
 <Slice>...</Slice>
 ...
</Partition>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Partition</a>
Child elements	None

## Remarks

The **Slice** element contains an MDX tuple expression or set expression that identifies the portion of the cube for which the partition stores information. The MDX expression is similar to the StrToSet MDX function with the CONSTRAINED keyword, in that the expression cannot include MDX or user-defined functions.

The element that corresponds to the parent of **Slice** in the Analysis Management Objects (AMO) object model is [Partition](#).

# SolveOrder Element (ASSL)

Article • 12/09/2022

Indicates the solve order in which the [CalculationProperty](#) element is applied to a calculated member or calculated cell definition.

## Syntax

XML

```
<CalculationProperty>
 ...
 <SolveOrder>...</SolveOrder>
 ...
</CalculationProperty>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Integer
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">CalculationProperty</a>
Child elements	None

## Remarks

The **SolveOrder** property applies to **CalculationProperty** elements with a **CalculationType** of *Member* or *Cells*.

The element that corresponds to the parent of **SolveOrder** in the Analysis Management Objects (AMO) object model is [CalculationProperty](#).

# Source Element (Binding) (ASSL)

Article • 12/09/2022

Identifies the source of data to which the parent element is bound.

## Syntax

XML

```
<AggregationInstance> <!-- or one of the elements listed below in the
Element Relationships table -->
...
<Source>...</Source>
...
</Cube>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

[ ] Expand table

Ancestor or Parent	Data Type
AggregationInstance	TabularBinding
AggregationInstanceMeasure	ColumnBinding
Cube	DataSourceViewBinding
DataItem	Any data type derived from <a href="#">Binding</a> , depending on the parent of <a href="#">DataItem</a> . For more information, see Remarks.
Dimension	<a href="#">CubeDimensionBinding</a> , <a href="#">DataSourceViewBinding</a> , <a href="#">DimensionBinding</a> , <a href="#">TimeBinding</a>

Ancestor or Parent	Data Type
DimensionAttribute	AttributeBinding, UserDefinedGroupBinding
MeasureGroup	MeasureGroupBinding
MeasureGroupDimension	MeasureGroupDimensionBinding
MiningStructure	CubeDimensionBinding, DataSourceViewBinding, DimensionBinding
Partition	TabularBinding
ProactiveCaching	Any data type derived from <a href="#">ProactiveCachingBinding</a> , depending on the processing and notification options used by the parent of the <a href="#">ProactiveCaching</a> element.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	AggregationInstance, AggregationInstanceMeasure, Cube, DataItem, Dimension, DimensionAttribute, MeasureGroup, MeasureGroupDimension, MiningStructure, Partition, ProactiveCaching.
Child elements	None

## Remarks

In the **Source** element, the derived **Binding** data types that are allowed in the **DataItem** element depend on the parent of the **DataItem** element.

[\[+\] Expand table](#)

DataItem Parent	Allowed Data Types
DimensionAttribute	AttributeBinding, ColumnBinding, TimeAttributeBinding (only for KeyColumns).
MeasureGroupAttribute	AttributeBinding, ColumnBinding, InheritedBinding.
ScalarMiningStructureColumn	ColumnBinding

For more information about the **Binding** type, including tables of Analysis Services Scripting Language (ASSL) objects of the **Binding** type and the inheritance hierarchy of **Binding** types, see [Binding Data Type \(ASSL\)](#).

 No

# SourceColumnID Element (ASSL)

Article • 12/09/2022

Contains the identifier (ID) of the source mining structure column in the ancestor [MiningStructure](#) element.

## Syntax

XML

```
<MiningModelColumn>
 ...
 <SourceColumnID>...</SourceColumnID>
 ...
</MiningModelColumn>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">MiningModelColumn</a>
Child elements	None

## Remarks

The value of the **SourceColumnID** element matches the identifier of a mining structure column in the [Columns](#) collection of the parent **MiningStructure**.

The element that corresponds to the parent of **SourceColumnID** in the Analysis Management Objects (AMO) object model is [MiningModelColumn](#).

# State Element (ASSL)

Article • 12/09/2022

Contains a read-only value that describes the current processing state of the parent element.

## Syntax

XML

```
<Cube> <!-- or Dimension, MeasureGroup, MiningModel, MiningStructure, Partition -->
...
<State>...</State>
...
</Cube>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">Dimension</a> , <a href="#">MeasureGroup</a> , <a href="#">MiningModel</a> , <a href="#">MiningStructure</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>Processed</i>	The element has been fully processed.
<i>PartiallyProcessed</i>	The element has been partially processed. ( <a href="#">Cube</a> and <a href="#">MeasureGroup</a> only.)
<i>Unprocessed</i>	The element has not been processed.

The enumeration that corresponds to the allowed values for **State** in the Analysis Management Objects (AMO) object model is [AnalysisState](#).

The elements that correspond to the parents of **State** in the Analysis Management Objects (AMO) object model are [Cube](#), [Dimension](#), [MeasureGroup](#), [MiningModel](#), [MiningStructure](#), and [Partition](#).

# Status Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression that returns a status indicator for a [Kpi](#) element.

## Syntax

XML

```
<Kpi>
 ...
 <Status>...</Status>
 ...
</Kpi>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Kpi</a>
Child elements	None

## Remarks

The **Status** element contains an MDX expression.

The element that corresponds to the parent of **Status** in the Analysis Management Objects (AMO) object model is [Kpi](#).

# StatusGraphic Element (ASSL)

Article • 12/09/2022

Contains the recommended graphical representation of the status of the [Kpi](#) element.

## Syntax

XML

```
<Kpi>
 ...
 <StatusGraphic>...</StatusGraphic>
 ...
</Kpi>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Kpi</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Traffic Light - Single</i>	Traffic light (single)
<i>Traffic Light - Multiple</i>	Traffic light (multiple)
<i>Road Signs</i>	Road signs
<i>Gauge - Ascending</i>	Gauge
<i>Gauge - Descending</i>	Reversed Gauge
<i>Thermometer</i>	Thermometer
<i>Cylinder</i>	Cylinder
<i>Smiley Face</i>	Face

The element that corresponds to the parent of **StatusGraphic** in the Analysis Management Objects (AMO) object model is [Kpi](#).

# StopTime Element (ASSL)

Article • 12/09/2022

Specifies the date and time at which a [Trace](#) element should stop.

## Syntax

XML

```
<Trace>
 ...
 <StopTime>...</StopTime>
 ...
</Trace>
```

## Element Characteristics

[+] [Expand table](#)

Characteristic	Description
Data type and length	DateTime
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Trace</a>
Child elements	None

The element that corresponds to the parent of **StopTime** in the Analysis Management Objects (AMO) object model is [Trace](#).

# StorageEngineUsed Element (XMLA)

Article • 12/09/2022

Contains a read-only value that describes the current database type.

## Syntax

XML

```
<Databases>
 <Database>
 <Name>...</Name>
 <ID>...</ID>
 <CreatedTimestamp>...</CreatedTimestamp>
 <LastSchemaUpdate>...</LastSchemaUpdate>
 <LastUpdate>...</LastUpdate>
 <Description>...</Description>
 <State> </State>
 <AggregationPrefix>...</AggregationPrefix>
 <EstimatedSize>...</EstimatedSize>
 <LastProcessed>...</LastProcessed>
 <Language>...</Language>
 <Collation>...</Collation>
 <Visible>...</Visible>
 <MasterDatasourceID>...</MasterDataSourceID>
 <Accounts>...</Accounts>
 <DataSources>...</DataSources>
 <DataSourceViews>...</DataSourceViews>
 <Dimensions>...</Dimensions>
 <Cubes>...</Cubes>
 <MiningStructures>...</MiningStructures>
 <Roles>...</Roles>
 <Assemblies>...</Assemblies>
 <DatabasePermissions>...</DatabasePermissions>
 <Translations>...</Translations>
 <Annotations>...</Annotations>
 <StorageEngineUsed >...</StorageEngineUsed>
 </Database>
</Databases>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">database</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>Traditional</i>	The database model corresponds to a MOLAP, ROLAP, or HOLAP storage mode.
<i>InMemory</i>	The database model corresponds to an IMBI storage mode.
<i>Mixed</i>	The database model mixes IMBI and MOLAP, ROLAP, or HOLAP storage modes.

The enumeration that corresponds to the allowed values for **StorageEngineUsed** in the Analysis Management Objects (AMO) object model is [StorageEngineUsed](#).

The elements that correspond to the parents of **StorageEngineUsed** in the Analysis Management Objects (AMO) object model are [Database](#).

# StorageLocation Element (ASSL)

Article • 12/09/2022

Contains the file system storage location for the contents of the parent element.

## Syntax

XML

```
<Cube><!-- or MeasureGroup, Partition -->
...
<StorageLocation>...</StorageLocation>
...
</Cube>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	See the table below.
Cardinality	0-1: Optional element that can occur once and only once.

[+] Expand table

Ancestor or Parent	Default Value
Cube	None
MeasureGroup	Value of <b>StorageLocation</b> from the <b>Cube</b> parent element.
Partition	Value of <b>StorageLocation</b> from the <b>MeasureGroup</b> parent element.

## Element Relationships

[+] Expand table

Relationship	Element
Parent elements	<a href="#">Cube</a> , <a href="#">MeasureGroup</a> , <a href="#">Partition</a>
Child elements	None

## Remarks

The elements that correspond to the parents of **StorageLocation** in the Analysis Management Objects (AMO) object model are [Cube](#), [MeasureGroup](#), and [Partition](#).

# StorageMode Element (ASSL)

Article • 12/09/2022

Determines the storage mode for the parent element.

## Syntax

XML

```
<Cube> <!-- or Dimension, MeasureGroup, Partition -->
...
<StorageMode>...</StorageMode>
...
</Cube>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>MOLAP</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">Cube Element (ASSL)</a> , <a href="#">Dimension Element (ASSL)</a> , <a href="#">MeasureGroup Element (ASSL)</a> , <a href="#">Partition Element (ASSL)</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[Expand table](#)

Value	Description
<i>MOLAP</i>	The parent uses multidimensional OLAP (MOLAP) storage.
<i>ROLAP</i>	The parent uses relational OLAP (ROLAP) storage.
<i>HOLAP</i>	The parent uses hybrid OLAP (HOLAP) storage.  Note: This value is not valid for <a href="#">Dimension</a> parent elements.
<i>InMemory</i>	The parent uses IMBI storage.

The enumeration that corresponds to the allowed values for **StorageMode** in the Analysis Management Objects (AMO) object model is [StorageMode](#).

The elements that correspond to the parents of **StorageMode** in the Analysis Management Objects (AMO) object model are [Cube](#), [Dimension](#), [MeasureGroup](#), and [Partition](#).

## See Also

[Properties \(ASSL\)](#)

---

## Feedback

 Yes

 No

# TableID Element (ASSL)

Article • 12/09/2022

Contains the identifier (ID) of the table (from the [DataSourceView](#) element) associated with the parent element.

## Syntax

XML

```
<ColumnBinding> <!-- or DSVTableBinding, RowBinding,
IncrementalProcessingNotification -->
...
 <TableID>...</TableID>
...
</ColumnBinding>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">ColumnBinding</a> , <a href="#">DSVTableBinding</a> , <a href="#">IncrementalProcessingNotification</a> , <a href="#">RowBinding</a>
Child elements	None

## Remarks

The table identified by **TableID** must be within the data source to which the owning object (dimension or cube) is bound.

The elements that correspond to the parents of **TableID** in the Analysis Management Objects (AMO) object model are Microsoft.AnalysisServices.ColumnBinding>, <xref:Microsoft.AnalysisServices.DSVTableBinding, Microsoft.AnalysisServices.IncrementalProcessingNotification, and Microsoft.AnalysisServices.RowBinding.

# Target Element (ASSL)

Article • 12/09/2022

Identifies the target of the [Action](#) element.

## Syntax

XML

```
<Action>
 ...
 <Target>...</Target>
 ...
</Action>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent element	<a href="#">Action</a>
Child elements	None

## Remarks

The expected value of this element depends on the value of the [TargetType](#) element for the parent **Action**. The following table describes the expected values of **Target** based on the value of **TargetType**.

[\[+\] Expand table](#)

TargetType value	Expected value
<i>Cube</i>	The name of a cube.
<i>Cells</i>	A subcube expression.
<i>Set</i>	A set expression or the name of a named set.  Note: A subselect statement cannot be used.
<i>Hierarchy, HierarchyMembers</i>	The name of a hierarchy.
<i>Dimension, DimensionMembers</i>	The name of a dimension.
<i>Level, LevelMembers</i>	The name of a level.
<i>Attribute, AttributeMembers</i>	The name of an attribute.

The element that corresponds to the parent of **Target** in the Analysis Management Objects (AMO) object model is [Action](#).

 No

# TargetType Element (ASSL)

Article • 12/09/2022

Identifies the item type of the item identified in the [Target](#) element.

## Syntax

XML

```
<Action>
 ...
 <TargetType>...</TargetType>
 ...
</Action>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Action</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Cube</i>	The target of the action is a cube.
<i>Cells</i>	The target of the action is a subcube.
<i>Set</i>	The target of the action is a set.
<i>Hierarchy</i>	The target of the action is a hierarchy.
<i>Level</i>	The target of the action is a level.
<i>DimensionMembers</i>	The target of the action is the members of a dimension.
<i>HierarchyMembers</i>	The target of the action is the members of a hierarchy.
<i>LevelMembers</i>	The target of the action is the members of a level.
<i>AttributeMembers</i>	The target of the action is the members of an attribute.

The enumeration that corresponds to the allowed values for **TargetType** in the Analysis Management Objects (AMO) object model is [ActionTargetType](#).

The element that corresponds to the parent of **TargetType** in the Analysis Management Objects (AMO) object model is [Action](#).

# Trend Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression that returns a trend indicator for a [Kpi](#) element.

## Syntax

XML

```
<Kpi>
 ...
 <Trend>...</Trend>
 ...
</Kpi>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Kpi</a>
Child elements	None

## Remarks

The **Trend** element contains an MDX expression that evaluates to a number between -1 and 1.

The element that corresponds to the parent of **Trend** in the Analysis Management Objects (AMO) object model is [Kpi](#).

# Trimming Element (ASSL)

Article • 12/09/2022

Specifies how data from the data source is trimmed.

## Syntax

XML

```
<DataItem>
 ...
 <Trimming>...</Trimming>
 ...
</DataItem>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Right</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">DataItem</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Left</i>	Data is trimmed on the left.
<i>Right</i>	Data is trimmed on the right.
<i>LeftRight</i>	Data is trimmed on the left and right.
<i>None</i>	Data is not trimmed.

The enumeration that corresponds to the allowed values for **Trimming** in the Analysis Management Objects (AMO) object model is [Trimming](#).

The element that corresponds to the parent of **Trimming** in the Analysis Management Objects (AMO) object model is [DataItem](#).

# Type Element (Action) (ASSL)

Article • 12/09/2022

Contains the type of the [Action](#) element.

## Syntax

XML

```
<Action>
 ...
 <Type>...</Type>
 ...
</Action>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent element	<a href="#">Action</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Url</i>	Displays a variable page in an Internet browser.
<i>Html</i>	Executes an HTML script in an Internet browser.
<i>Statement</i>	Executes an OLE DB command.
<i>DrillThrough</i>	<p>Retrieves a rowset for drillthrough.</p> <p>This value is identical to <i>Rowset</i> and identifies drillthrough actions. It can only be used on actions whose <a href="#">TargetType</a> value is set to <i>Cells</i>.</p>
<i>DataSet</i>	Retrieves a dataset.
<i>Rowset</i>	Retrieves a rowset.
<i>CommandLine</i>	Executes a command at a command prompt.
<i>Proprietary</i>	Performs an operation using an interface different than those listed earlier in this table.
<i>Report</i>	<p>Displays a variable page in an Internet browser.</p> <p>This value is identical to <i>Url</i> and identifies report actions.</p>

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [Action](#).

# Type Element (Dimension) (ASSL)

Article • 12/09/2022

Provides information about the contents of the dimension.

## Syntax

XML

```
<Dimension>
 ...
 <Type>...</Type>
 ...
</Dimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	Dimension
Child elements	None

## Remarks

Some values for **Type**, for example *Accounts*, determine specific behavior.

The value of this element is limited to one of the strings listed in the following table.

[] [Expand table](#)

<b>Value</b>	<b>Description</b>
<i>Regular</i>	The dimension is a regular dimension.
<i>Time</i>	The dimension is a time dimension.  Note: This value indicates that the dimension supports functionality specific to time dimensions.
<i>Geography</i>	The dimension contains geographical attributes.
<i>Organization</i>	The dimension contains organizational attributes.
<i>BillOfMaterials</i>	The dimension contains bill of materials attributes.
<i>Accounts</i>	The dimension contains account-related attributes.  Note: This value indicates that the dimension supports functionality specific to account dimensions.
<i>Customers</i>	The dimension contains customer-related attributes.
<i>Products</i>	The dimension contains product-related attributes.
<i>Scenario</i>	The dimension contains scenario-related attributes.
<i>Quantitative</i>	The dimension contains quantitative attributes.
<i>Utility</i>	The dimension contains utility attributes.
<i>Currency</i>	The dimension contains currency attributes.
<i>Rates</i>	The dimension contains exchange rate attributes.
<i>Channel</i>	The dimension contains channel attributes.
<i>Promotion</i>	The dimension contains promotion-related attributes.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [DimensionType](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [Dimension](#).

The value of this element is limited to one of the strings listed in the following table.

[Expand table](#)

Value	Description
<i>Account</i>	The attribute represents the name of an account.
<i>AccountNumber</i>	The attribute represents the number of an account.
<i>AccountType</i>	The attribute represents the type of an account.
<i>Address</i>	The attribute represents an address.
<i>AddressBuilding</i>	The attribute represents a building identifier for an address.
<i>AddressCity</i>	The attribute represents a city for an address.
<i>AddressCountry</i>	The attribute represents a country or region for an address.
<i>AddressFax</i>	The attribute represents a fax telephone number.
<i>AddressFloor</i>	The attribute represents a floor identifier for an address.
<i>AddressHouse</i>	The attribute represents a house number for an address.
<i>AddressPhone</i>	The attribute represents a telephone number.
<i>AddressQuarter</i>	The attribute represents a quarter for an address.
<i>AddressRoom</i>	The attribute represents a room identifier for an address.
<i>AddressStateOrProvince</i>	The attribute represents a state or province for an address.
<i>AddressStreet</i>	The attribute represents the street for an address.
<i>AddressZip</i>	The attribute represents a postal code (ZIP code) for an address.
<i>BOMResource</i>	The attribute represents a resource for a bill of materials (BOM).
<i>Caption</i>	The attribute represents a caption.
<i>CaptionAbbreviation</i>	The attribute represents an abbreviation.
<i>CaptionDescription</i>	The attribute represents a description.
<i>Channel</i>	The attribute represents a channel.
<i>City</i>	The attribute represents a city.
<i>Company</i>	The attribute represents a company.

Value	Description
<i>Continent</i>	The attribute represents a continent.
<i>Country</i>	The attribute represents a country or region.
<i>County</i>	The attribute represents a county.
<i>CurrencyDestination</i>	The attribute represents the destination currency of a currency exchange.
<i>CurrencyISOcode</i>	The attribute represents the ISO code of a currency.
<i>CurrenName</i>	The attribute represents the name of a currency.
<i>CurrencySource</i>	The attribute represents the source currency of a currency exchange.
<i>CustomerGroup</i>	The attribute represents a group of customers.
<i>CustomerHousehold</i>	The attribute represents a household of customers.
<i>Customers</i>	The attribute represents a customer.
<i>Date</i>	The attribute represents a date.
<i>DateCanceled</i>	The attribute represents a cancellation date.
<i>DateDuration</i>	The attribute represents a duration.
<i>DateEnded</i>	The attribute represents an end date.
<i>DateModified</i>	The attribute represents a modification date.
<i>DateStart</i>	The attribute represents a start date.
<i>DayOfHalfYears</i>	The attribute represents the day ordinal of a half-year.
<i>DayOfMonth</i>	The attribute represents the day ordinal of a month.
<i>DayOfQuarter</i>	The attribute represents the day ordinal of a quarter.
<i>DayOfTrimester</i>	The attribute represents the day ordinal of a trimester.
<i>DayOfWeek</i>	The attribute represents the day ordinal of a week.
<i>DayOfYear</i>	The attribute represents the day ordinal of a year.
<i>Days</i>	The attribute represents days.
<i>DaysOfTenDays</i>	The attribute represents the day ordinal of a ten-day period.
<i>FiscalDay</i>	The attribute represents days in a fiscal calendar.

Value	Description
<i>FiscalDayOfHalfYears</i>	The attribute represents the day ordinal of a half-year in a fiscal calendar.
<i>FiscalDayOfMonth</i>	The attribute represents the day ordinal of a month in a fiscal calendar.
<i>FiscalDayOfQuarter</i>	The attribute represents the day ordinal of a quarter in a fiscal calendar.
<i>FiscalDayOfTrimester</i>	The attribute represents the day ordinal of a trimester in a fiscal calendar.
<i>FiscalDayOfWeek</i>	The attribute represents the day ordinal of a week in a fiscal calendar.
<i>FiscalDayOfYear</i>	The attribute represents the day ordinal of a year in a fiscal calendar.
<i>FiscalHalfYears</i>	The attribute represents half-years in a fiscal calendar.
<i>FiscalHalfYearsOfYear</i>	The attribute represents the half-year ordinal of a year in a fiscal calendar.
<i>FiscalMonth</i>	The attribute represents months in a fiscal calendar.
<i>FiscalMonthOfHalfYears</i>	The attribute represents the month ordinal of a half-year in a fiscal calendar.
<i>FiscalMonthOfQuarter</i>	The attribute represents the month ordinal of a quarter in a fiscal calendar.
<i>FiscalMonthOfTrimester</i>	The attribute represents the month ordinal of a trimester in a fiscal calendar.
<i>FiscalMonthOfYear</i>	The attribute represents the month ordinal of a year in a fiscal calendar.
<i>FiscalQuarter</i>	The attribute represents quarters in a fiscal calendar.
<i>FiscalQuarterOfHalfYear</i>	The attribute represents the quarter ordinal of a half-year in a fiscal calendar.
<i>FiscalQuarterOfYear</i>	The attribute represents the quarter ordinal of a year in a fiscal calendar.
<i>FiscalTrimester</i>	The attribute represents trimesters in a fiscal calendar.
<i>FiscalTrimesterOfYear</i>	The attribute represents the trimester ordinal of a year in a fiscal calendar.

Value	Description
<i>FiscalWeek</i>	The attribute represents weeks in a fiscal calendar.
<i>FiscalWeekOfHalfYears</i>	The attribute represents the week ordinal of a half-year in a fiscal calendar.
<i>FiscalWeekOfMonth</i>	The attribute represents the week ordinal of a month in a fiscal calendar.
<i>FiscalWeekOfQuarter</i>	The attribute represents the week ordinal of a quarter in a fiscal calendar.
<i>FiscalWeekOfTrimester</i>	The attribute represents the week ordinal of a trimester in a fiscal calendar.
<i>FiscalWeekOfYear</i>	The attribute represents the week ordinal of a year in a fiscal calendar.
<i>FiscalYear</i>	The attribute represents years in a fiscal calendar.
<i>FormattingColor</i>	The attribute represents the color used in formatting.
<i>FormattingFont</i>	The attribute represents the font used in formatting.
<i>FormattingFontEffects</i>	The attribute represents the font effects used in formatting.
<i>FormattingFontSize</i>	The attribute represents the font size used in formatting.
<i>FormattingOrder</i>	The attribute represents the order used in formatting.
<i>FormattingSubtotal</i>	The attribute represents a subtotal.
<i>GeoBoundaryBottom</i>	The attribute represents the bottommost value of a geographic boundary.
<i>GeoBoundaryFront</i>	The attribute represents the frontmost value of a geographic boundary.
<i>GeoBoundaryLeft</i>	The attribute represents the leftmost value of a geographic boundary.
<i>GeoBoundaryPolygon</i>	The attribute represents the polygon definition of a geographic boundary.
<i>GeoBoundaryRear</i>	The attribute represents the rearmost value of a geographic boundary.
<i>GeoBoundaryRight</i>	The attribute represents the rightmost value of a geographic boundary.
<i>GeoBoundaryTop</i>	The attribute represents the topmost value of a geographic

Value	Description
	boundary.
<i>GeoCentroidX</i>	The attribute represents an X-axis centroid for a geographic region.
<i>GeoCentroidY</i>	The attribute represents a Y-axis centroid for a geographic region.
<i>GeoCentroidZ</i>	The attribute represents a Z-axis centroid for a geographic region.
<i>HalfYears</i>	The attribute represents half-years.
<i>HalfYearsOfYear</i>	The attribute represents the half-year ordinal of a year.
<i>Hours</i>	The attribute represents hours.
<i>Id</i>	The attribute represents an identifier or key.
<i>IsHoliday</i>	The attribute indicates whether a date is a holiday.
<i>ISO8601DayOfWeek</i>	The attribute represents the day ordinal of a week in an ISO 8601 calendar.
<i>ISO8601DayOfYear</i>	The attribute represents the day ordinal of a year in an ISO 8601 calendar.
<i>ISO8601Days</i>	The attribute represents days in an ISO 8601 calendar.
<i>ISO8601Week</i>	The attribute represents weeks in an ISO 8601 calendar.
<i>ISO8601WeekOfYear</i>	The attribute represents the week ordinal of a year in an ISO 8601 calendar.
<i>ISO8601Year</i>	The attribute represents years in an ISO 8601 calendar.
<i>IsWeekDay</i>	The attribute indicates whether a date is a weekday.
<i>IsWorkingDay</i>	The attribute indicates whether a date is a working day.
<i>ManufacturingDay</i>	The attribute represents days in a manufacturing calendar.
<i>ManufacturingDayOfHalfYears</i>	The attribute represents the day ordinal of a half-year in a manufacturing calendar.
<i>ManufacturingDayOfMonth</i>	The attribute represents the day ordinal of a month in a manufacturing calendar.
<i>ManufacturingDayOfQuarter</i>	The attribute represents the day ordinal of a quarter in a manufacturing calendar.

Value	Description
<i>ManufacturingDayOfTrimester</i>	The attribute represents the day ordinal of a trimester in a manufacturing calendar.
<i>ManufacturingDayOfWeek</i>	The attribute represents the day ordinal of a week in a manufacturing calendar.
<i>ManufacturingDayOfYear</i>	The attribute represents the day ordinal of a year in a manufacturing calendar.
<i>ManufacturingHalfYears</i>	The attribute represents half-years in a manufacturing calendar.
<i>ManufacturingHalfYearsOfYear</i>	The attribute represents the half-year ordinal of a year in a manufacturing calendar.
<i>ManufacturingMonth</i>	The attribute represents months in a manufacturing calendar.
<i>ManufacturingMonthOfHalfYears</i>	The attribute represents the month ordinal of a half-year in a manufacturing calendar.
<i>ManufacturingMonthOfQuarter</i>	The attribute represents the month ordinal of a quarter in a manufacturing calendar.
<i>ManufacturingMonthOfTrimester</i>	The attribute represents the month ordinal of a trimester in a manufacturing calendar.
<i>ManufacturingMonthOfYear</i>	The attribute represents the month ordinal of a year in a manufacturing calendar.
<i>ManufacturingQuarter</i>	The attribute represents quarters in a manufacturing calendar.
<i>ManufacturingQuarterOfHalfYear</i>	The attribute represents the quarter ordinal of a half-year in a manufacturing calendar.
<i>ManufacturingQuarterOfYear</i>	The attribute represents the quarter ordinal of a year in a manufacturing calendar.
<i>ManufacturingTrimester</i>	The attribute represents trimesters in a manufacturing calendar.
<i>ManufacturingTrimesterOfYear</i>	The attribute represents the trimester ordinal of a year in a manufacturing calendar.
<i>ManufacturingWeek</i>	The attribute represents weeks in a manufacturing calendar.
<i>ManufacturingWeekOfHalfYears</i>	The attribute represents the week ordinal of a half-year in a manufacturing calendar.
<i>ManufacturingWeekOfMonth</i>	The attribute represents the week ordinal of a month in a manufacturing calendar.

Value	Description
<i>ManufacturingWeekOfQuarter</i>	The attribute represents the week ordinal of a quarter in a manufacturing calendar.
<i>ManufacturingWeekOfTrimester</i>	The attribute represents the week ordinal of a trimester in a manufacturing calendar.
<i>ManufacturingWeekOfYear</i>	The attribute represents the week ordinal of a year in a manufacturing calendar.
<i>ManufacturingYear</i>	The attribute represents years in a manufacturing calendar.
<i>Minutes</i>	The attribute represents minutes.
<i>MonthOfHalfYears</i>	The attribute represents the month ordinal of a half-year.
<i>MonthOfQuarter</i>	The attribute represents the month ordinal of a quarter.
<i>MonthOfTrimester</i>	The attribute represents the month ordinal of a trimester.
<i>MonthOfYear</i>	The attribute represents the month ordinal of a year.
<i>Months</i>	The attribute represents months.
<i>OrganizationalUnit</i>	The attribute represents an organizational unit.
<i>OrgTitle</i>	The attribute represents an organizational title.
<i>PercentOwnership</i>	The attribute represents a percent of ownership.
<i>PercentVoteRight</i>	The attribute represents a percent of voting rights.
<i>Person</i>	The attribute represents a person.
<i>PersonContact</i>	The attribute represents contact information for a person.
<i>PersonDemographic</i>	The attribute represents demographic information for a person.
<i>PersonFirstName</i>	The attribute represents the given name (first name) of a person.
<i>PersonFullName</i>	The attribute represents the full name of a person.
<i>PersonLastName</i>	The attribute represents the surname (last name) of a person.
<i>PersonMiddleName</i>	The attribute represents the middle name of a person.
<i>PhysicalColor</i>	The attribute represents a color.
<i>PhysicalDensity</i>	The attribute represents density.

Value	Description
<i>PhysicalDepth</i>	The attribute represents depth.
<i>PhysicalHeight</i>	The attribute represents height.
<i>PhysicalSize</i>	The attribute represents a size.
<i>PhysicalVolume</i>	The attribute represents volume.
<i>PhysicalWeight</i>	The attribute represents weight.
<i>PhysicalWidth</i>	The attribute represents width.
<i>Point</i>	The attribute represents a point.
<i>PostalCode</i>	The attribute represents a postal code.
<i>Product</i>	The attribute represents a product.
<i>ProductBrand</i>	The attribute represents a product brand.
<i>ProductCategory</i>	The attribute represents a product category.
<i>ProductGroup</i>	The attribute represents a product group.
<i>ProductSKU</i>	The attribute represents a product stock keeping unit (SKU).
<i>ProjectCode</i>	The attribute represents a project code.
<i>Projectcompletion</i>	The attribute represents the completion status of a project.
<i>ProjectEnddate</i>	The attribute represents a project end date.
<i>ProjectName</i>	The attribute represents a project name.
<i>ProjectStartDate</i>	The attribute represents a project start date.
<i>Promotion</i>	The attribute represents a promotion.
<i>QtyRangeHigh</i>	The attribute represents the highest value of a range of quantities.
<i>QtyRangeLow</i>	The attribute represents the lowest value of a range of quantities.
<i>Quantitative</i>	The attribute represents a quantitative attribute.
<i>QuarterOfHalfYear</i>	The attribute represents the quarter ordinal of a half-year.
<i>QuarterOfYear</i>	The attribute represents the quarter ordinal of a year.
<i>Quarters</i>	The attribute represents quarters.

Value	Description
<i>Rate</i>	The attribute represents a rate.
<i>RateType</i>	The attribute represents a rate type.
<i>Region</i>	The attribute represents a customer-defined region.
<i>Regular</i>	The attribute represents a regular attribute.
<i>RelationToParent</i>	The attribute represents a relation to a parent.
<i>ReportingDay</i>	The attribute represents days in a reporting calendar.
<i>ReportingDayOfHalfYears</i>	The attribute represents the day ordinal of a half-year in a reporting calendar.
<i>ReportingDayOfMonth</i>	The attribute represents the day ordinal of a month in a reporting calendar.
<i>ReportingDayOfQuarter</i>	The attribute represents the day ordinal of a quarter in a reporting calendar.
<i>ReportingDayOfTrimester</i>	The attribute represents the day ordinal of a trimester in a reporting calendar.
<i>ReportingDayOfWeek</i>	The attribute represents the day ordinal of a week in a reporting calendar.
<i>ReportingDayOfYear</i>	The attribute represents the day ordinal of a year in a reporting calendar.
<i>ReportingHalfYears</i>	The attribute represents half-years in a reporting calendar.
<i>ReportingHalfYearsOfYear</i>	The attribute represents the half-year ordinal of a year in a reporting calendar.
<i>ReportingMonth</i>	The attribute represents months in a reporting calendar.
<i>ReportingMonthOfHalfYears</i>	The attribute represents the month ordinal of a half-year in a reporting calendar.
<i>ReportingMonthOfQuarter</i>	The attribute represents the month ordinal of a quarter in a reporting calendar.
<i>ReportingMonthOfTrimester</i>	The attribute represents the month ordinal of a trimester in a reporting calendar.
<i>ReportingMonthOfYear</i>	The attribute represents the month ordinal of a year in a reporting calendar.
<i>ReportingQuarter</i>	The attribute represents quarters in a reporting calendar.

Value	Description
<i>ReportingQuarterOfHalfYear</i>	The attribute represents the quarter ordinal of a half-year in a reporting calendar.
<i>ReportingQuarterOfYear</i>	The attribute represents the quarter ordinal of a year in a reporting calendar.
<i>ReportingTrimester</i>	The attribute represents trimesters in a reporting calendar.
<i>ReportingTrimesterOfYear</i>	The attribute represents the trimester ordinal of a year in a reporting calendar.
<i>ReportingWeek</i>	The attribute represents weeks in a reporting calendar.
<i>ReportingWeekOfHalfYears</i>	The attribute represents the week ordinal of a half-year in a reporting calendar.
<i>ReportingWeekOfMonth</i>	The attribute represents the week ordinal of a month in a reporting calendar.
<i>ReportingWeekOfQuarter</i>	The attribute represents the week ordinal of a quarter in a reporting calendar.
<i>ReportingWeekOfTrimester</i>	The attribute represents the week ordinal of a trimester in a reporting calendar.
<i>ReportingWeekOfYear</i>	The attribute represents the week ordinal of a year in a reporting calendar.
<i>ReportingYear</i>	The attribute represents years in a reporting calendar.
<i>Representative</i>	The attribute represents a representative.
<i>Scenario</i>	The attribute represents a scenario.
<i>Seconds</i>	The attribute represents seconds.
<i>Sequence</i>	The attribute represents a sequence attribute.
<i>ShortCaption</i>	The attribute represents a short caption.
<i>StateOrProvince</i>	The attribute represents a state or province.
<i>TenDayOfHalfYears</i>	The attribute represents the ten-day period ordinal of a half-year.
<i>TenDayOfQuarter</i>	The attribute represents the ten-day period ordinal of a quarter.
<i>TenDayOfTrimester</i>	The attribute represents the ten-day period ordinal of a trimester.

Value	Description
<i>TenDayOfYear</i>	The attribute represents the ten-day period ordinal of a year.
<i>TenDays</i>	The attribute represents ten-day periods.
<i>TenDaysOfMonth</i>	The attribute represents the ten-day period ordinal of a month.
<i>Trimester</i>	The attribute represents trimesters.
<i>TrimesterOfYear</i>	The attribute represents the trimester ordinal of a year.
<i>UndefinedTime</i>	The attribute represents an undefined time period.
<i>Utility</i>	The attribute represents a utility.
<i>Version</i>	The attribute represents a version.
<i>WebHtml</i>	The attribute represents HTML content.
<i>WebMailAlias</i>	The attribute represents an e-mail alias.
<i>WebUrl</i>	The attribute represents a URL address.
<i>WebXmlOrXsl</i>	The attribute represents XML or XSL content.
<i>WeekOfHalfYears</i>	The attribute represents the week ordinal of a half-year.
<i>WeekOfMonth</i>	The attribute represents the week ordinal of a month.
<i>WeekOfQuarter</i>	The attribute represents the week ordinal of a quarter.
<i>WeekOfTrimester</i>	The attribute represents the week ordinal of a trimester.
<i>WeekOfYear</i>	The attribute represents the week ordinal of a year.
<i>Weeks</i>	The attribute represents weeks.
<i>Years</i>	The attribute represents years.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [AttributeType](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [DimensionAttribute](#).

# Type Element (MeasureGroup) (ASSL)

Article • 12/09/2022

Specifies the type of the [MeasureGroup](#).

## Syntax

XML

```
<MeasureGroup>
 ...
 <Type>...</Type>
 ...
</MeasureGroup>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MeasureGroup</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Regular</i>	Contains regular measures.
<i>ExchangeRate</i>	Contains foreign exchange rate measures.
<i>Sales</i>	Contains sales measures.
<i>Budget</i>	Contains budget measures.
<i>FinancialReporting</i>	Contains financial reporting measures.
<i>Marketing</i>	Contains marketing measures.
<i>Inventory</i>	Contains inventory measures.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [MeasureGroupType](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [MeasureGroup](#).

# Type Element (MeasureGroupAttribute) (ASSL)

Article • 12/09/2022

Contains the type of a [MeasureGroupAttribute](#) element.

## Syntax

XML
<pre>&lt;MeasureGroupAttribute&gt;   ...     &lt;Type&gt;...&lt;/Type&gt;   ... &lt;/MeasureGroupAttribute&gt;</pre>

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Regular</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent element	<a href="#">MeasureGroupAttribute</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>Regular</i>	Represents a regular attribute.
<i>Granularity</i>	Represents a granularity attribute.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [MeasureGroupAttributeType](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [MeasureGroupAttribute](#).

# Type Element (MiningStructureColumn) (ASSL)

Article • 12/09/2022

Contains the type of the [MiningStructureColumn](#) element.

## Syntax

```
XML

<MiningStructureColumn>
 ...
 <Type>...</Type>
 ...
</MiningStructureColumn>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningStructureColumn</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[] Expand table

Value	Description
<i>Long</i>	A 64-bit signed integer. This data type maps to the <b>Int64</b> data type in the .NET Framework and the DBTYPE_I8 data type in OLE DB.
<i>Boolean</i>	A Boolean value. This data type maps to the <b>Boolean</b> data type in the .NET Framework and the DBTYPE_BOOL data type in OLE DB.
<i>Text</i>	A null-terminated stream of Unicode characters. This data type maps to the <b>String</b> data type in the .NET Framework and the DBTYPE_WSTR data type in OLE DB.
<i>Double</i>	A double-precision floating point number within the range -1.79E +308 through 1.79E +308. This data type maps to the <b>Double</b> data type in the .NET Framework and the DBTYPE_R8 data type in OLE DB.
<i>Date</i>	Date data, stored as a double-precision floating point number. The whole portion is the number of days since December 30, 1899, while the fractional portion is a fraction of a day. This data type maps to the <b>DateTime</b> data type in the .NET Framework and the DBTYPE_DATE data type in OLE DB.
<i>Table</i>	A nested table. This data type maps to the DBTYPE_HCHAPTER data type in OLE DB.  Note: Table columns in the .NET Framework do not have an equivalent intrinsic data type, but are instead supported by the <b>DataReader</b> class.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [MiningStructureColumnTypes](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [MiningStructureColumn](#).

# Type Element (Partition) (ASSL)

Article • 12/09/2022

Contains the type of the [Partition](#) element.

## Syntax

XML

```
<Partition>
 ...
 <Type>...</Type>
 ...
</Partition>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>Data</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Partition</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Data</i>	The partition contains fact table data.
<i>Writeback</i>	The partition contains writeback table data.

The enumeration that corresponds to the allowed values for **Type** in the Analysis Management Objects (AMO) object model is [PartitionType](#).

The element that corresponds to the parent of **Type** in the Analysis Management Objects (AMO) object model is [Partition](#).

# UnknownMember Element (ASSL)

Article • 12/09/2022

Indicates whether the unknown member is visible.

## Syntax

XML

```
<Dimension>
 ...
 <UnknownMember>...</UnknownMember>
 ...
</Dimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Dimension</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>Visible</i>	The unknown member exists and is displayed.
<i>Hidden</i>	The unknown member exists but is not displayed.
<i>None</i>	The unknown member is not used.

The enumeration that corresponds to the allowed values for **UnknownMember** in the Analysis Management Objects (AMO) object model is [UnknownMemberBehavior](#).

# UnknownMemberName Element (ASSL)

Article • 12/09/2022

Contains the caption, in the default language of the dimension, for the unknown member of the dimension.

## Syntax

XML

```
<Dimension>
 ...
 <UnknownMemberName>...</UnknownMemberName>
 ...
</Dimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	<i>Unknown</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Dimension</a>
Child elements	None

## Remarks

The value of the **UnknownMemberName** element supplies the caption used for the unknown member. The member ID of the unknown member is *Dimension.UnknownMember*, where *Dimension* is the unique name of the dimension, and cannot be changed.

The element that corresponds to the parent of **UnknownMemberName** in the Analysis Management Objects (AMO) object model is [Dimension](#).

# Usage Element (MiningModelColumn) (ASSL)

Article • 12/09/2022

Describes how the associated column in the parent [MiningStructure](#) is used.

## Syntax

```
XML

<MiningModelColumn>
 ...
 <Usage>...</Usage>
 ...
</MiningModelColumn>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">MiningModelColumn</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[\] Expand table](#)

Value	Description
<i>Key</i>	The column is a key column.
<i>Input</i>	The column is an input column.
<i>Predict</i>	The column is a prediction column.
<i>PredictOnly</i>	The column is a prediction column only.
<i>None</i>	The column is not used by the model.  ** Warning ** When the value of Usage is "None", Analysis Services does not send any value to the server by default; hence, the Usage attribute is not included in the request/response.

The enumeration that corresponds to the allowed values for **Usage** in the Analysis Management Objects (AMO) object model is [MiningModelColumnUsages](#).

# Value Element (ASSL)

Article • 12/09/2022

Contains the value of the parent element.

## Syntax

XML

```
<AlgorithmParameter> <!-- or one of the elements listed below in the Element
Relationships table -->
...
<Value>...</Value>
...
</AlgorithmParameter>
```

## Element Characteristics

[\[+\] Expand table](#)

Characteristic	Description
Data type and length	See the table below.
Default value	None
Cardinality	1-1: Required element that occurs once and only once.

[\[+\] Expand table](#)

Ancestor or Parent	Data Type
AlgorithmParameter	Any simpleType
ServerProperty	Any simpleType
All others	String

## Element Relationships

[\[+\] Expand table](#)

Relationship	Element
Parent elements	<a href="#">AlgorithmParameter</a> , <a href="#">Annotation</a> , <a href="#">Kpi</a> , <a href="#">ReportFormatParameter</a> , <a href="#">ReportParameter</a> , <a href="#">ServerProperty</a>
Child elements	None

## Remarks

The **Value** element contains the value associated with the parent object. The expected value of the **Value** element varies depending on the parent element, as described in the following table.

[Expand table](#)

Parent element	Expected value
<a href="#">AlgorithmParameter</a>	The value of the algorithm parameter.
<a href="#">Annotation</a>	The value of the annotation.
<a href="#">Kpi</a>	A Multidimensional Expressions (MDX) expression used to calculate the value of the key performance indicator (KPI).
<a href="#">ReportFormatParameter</a>	The value of the report format parameter.
<a href="#">ReportParameter</a>	An MDX expression used to calculate the value of the report parameter.
<a href="#">ServerProperty</a>	The value of the server property for the currently running instance.

The elements that correspond to the parents of **Value** in the Analysis Management Objects (AMO) object model are [AlgorithmParameter](#), [Annotation](#), [Kpi](#), [ReportParameter](#), and [ServerProperty](#).

# Version Element (ASSL)

Article • 12/09/2022

Contains the read-only version number of the instance of Analysis Services represented by the [Server](#) element.

## Syntax

XML

```
<Server>
 ...
 <Version>...</Version>
 ...
</Server>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Server</a>
Child elements	None

## Remarks

The **Version** element describes which version of Analysis Services is installed.

The element that corresponds to the parent of **Version** in the Analysis Management Objects (AMO) object model is [Server](#).

# Visibility Element (ASSL)

Article • 12/09/2022

Defines the visibility of an [Annotation](#) element.

## Syntax

XML

```
<Annotation>
 ...
 <Visibility>...</Visibility>
 ...
</Annotation>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent element	<a href="#">Annotation</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

Value	Description
<i>SchemaRowset</i>	The annotation is visible in the schema rowset.
<i>None</i>	The annotation is not visible.

The enumeration that corresponds to the allowed values for **Visibility** in the Analysis Management Objects (AMO) object model is [Annotation](#).

# Visible Element (ASSL)

Article • 12/09/2022

Determines the visibility of the parent element.

## Syntax

XML

```
<CalculationProperty> <!-- or one of the elements listed below in the
Element Relationships table -->

<Visible>...</Visible>

</CalculationProperty>
```

## Element Characteristics

[ ] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	True
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] Expand table

Relationship	Element
Parent elements	<a href="#">CalculationProperty</a> , <a href="#">Cube</a> , <a href="#">CubeDimension</a> , <a href="#">CubeHierarchy</a> , <a href="#">Database</a> , <a href="#">Measure</a> , <a href="#">MemberProperty</a>
Child elements	None

## Remarks

The **Visible** element determines whether user interface components should display the parent element.

The elements that correspond to the parents of **Visible** in the Analysis Management Objects (AMO) object model are [CalculationProperty](#), [Cube](#), [CubeDimension](#), [CubeHierarchy](#), [Database](#), and [Measure](#).

# VisualTotals Element (ASSL)

Article • 12/09/2022

Contains a Multidimensional Expressions (MDX) expression that determines whether visual totals are displayed for members of this attribute.

## Syntax

XML

```
<AttributePermission>
 ...
 <VisualTotals>...</VisualTotals>
 ...
</AttributePermission>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	String
Default value	0
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">AttributePermission</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **VisualTotals** in the Analysis Management Objects (AMO) object model is [AttributePermission](#).

# Write Element (ASSL)

Article • 12/09/2022

Determines whether data or metadata can be written for a given [CubeDimensionPermission](#) or [Permission](#) element.

## Syntax

XML

```
<CubeDimensionPermission> <!-- or Permission -->
...
<Write>...</Write>
...
</CubeDimensionPermission>
```

## Element Characteristics

[ ] [Expand table](#)

Characteristic	Description
Data type and length	String (enumeration)
Default value	<i>None</i>
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[ ] [Expand table](#)

Relationship	Element
Parent elements	<a href="#">CubeDimensionPermission</a> , <a href="#">Permission</a>
Child elements	None

## Remarks

The value of this element is limited to one of the strings listed in the following table.

[\[+\] Expand table](#)

Value	Description
<i>None</i>	No access is permitted to data or metadata from the parent object.
<i>Allowed</i>	Write access is permitted to data and metadata from the parent object.

The elements that correspond to the parents of **Write** in the Analysis Management Objects (AMO) object model are [CubeDimensionPermission](#) and [Permission](#).

## See Also

# WriteEnabled Element (ASSL)

Article • 12/09/2022

Indicates whether dimension writebacks are available (subject to security permissions).

## Syntax

XML

```
<Dimension>
 ...
 <WriteEnabled>...</WriteEnabled>
 ...
</Dimension>
```

## Element Characteristics

[+] Expand table

Characteristic	Description
Data type and length	Boolean
Default value	None
Cardinality	0-1: Optional element that can occur once and only once.

## Element Relationships

[+] Expand table

Relationship	Element
Parent element	<a href="#">Dimension</a>
Child elements	None

## Remarks

The element that corresponds to the parent of **WriteEnabled** in the Analysis Management Objects (AMO) object model is [Dimension](#).

# Conceptual Schema Definition Language (CSDLBI) overview

Article • 10/31/2023

Applies to:  SQL Server Analysis Services  Azure Analysis Services  Fabric/Power BI Premium

Analysis Services supports the presentation of the definition of multidimensional models and tabular models at the 1103 and lower compatibility levels in an XML format called Conceptual Schema Definition Language with Business Intelligence annotations (CSDLBI). This article provides an overview of CSDLBI and how it is used with Analysis Services data models.

## Understanding the Role of CSDL

The Conceptual Schema Data Language (CSDL) is an XML-based language that describes entities, relationships, and functions. CSDL is defined as part of the Entity Data Framework. The BI annotations are an extension designed to support data modeling using Analysis Services.

Although CSDL is compliant with the Entity Data Framework, you do not need to understand the entity-relationship model or have any special tools to build a tabular model or a report based on a model. You build models by using client tools such as Visual Studio with Analysis Services projects extensions, also known as SQL Server Data Tools (SSDT), or an API such as AMO and deploy the model to a server.

The CSDLBI schema is generated by the Analysis Services server in response to a request for a model definition from a client. The client application sends an XML query to the Analysis Services server that hosts the model data. In response, the server sends an XML message containing a definition of the entities in the model, using the CSDLBI annotations. The reporting client then uses the information to present the fields, aggregations, and measures that are available in the model. The CSDLBI annotations also provide information about how to group, sort, and format the data.

## Working with CSDL

The set of CSDLBI annotations that represents any particular tabular model is an XML document containing a collection of entities, both simple and complex. The entities define tables (or dimensions), columns (attributes), associations (relationships), and formulas included in calculated columns, measure, or KPIs.

You cannot modify these objects directly, but must use the client tools and application programming interfaces (APIs) provided for working with tabular models.

You can obtain the CSDL for a model by sending a DISCOVER request to the server that hosts the model. The request must be qualified by specifying the server and the model, and, optionally, a view or perspective. The returned message is an XML string. Certain elements are language-dependent and may return different values depending on the language of the current connection. For more information, see [DISCOVER\\_CSDL\\_METADATA Rowset](#).

## CSDLBI Reference

The original CSDL specification (from the Entity Data Framework) provides for most of the entities and properties that are needed to support modeling. The BI annotations support special requirements of tabular models, reporting properties required for clients, and additional metadata required for multidimensional models.

Beginning in 2012, version 1.0 and subsequent versions of the CSDLBI specification are described in [Open Specifications](#). The Open Specification is updated periodically to coincide with changes in functionality. Prior to publishing CSDLBI to the Open Specification, CSDLBI versions 1.0 and 1.1 were documented as a reference on MSDN\TechNet. This early version of the CSDLBI reference provides more in-depth definitions of CSDLBI structures and semantics than provided in the open specification, however, the open specification should be used.

Fabric/Power BI Premium

## References

### Tabular Model Scripting Language (TMSL)

A command and object model definition syntax for tabular models at compatibility level 1200 or higher. TMSL communicates through the XMLA protocol, where the XMLA.Execute method accepts both JSON-based and ASSL-based scripts.

### Tabular Object Model (TOM)

TOM is an extension of the Analysis Management Object (AMO) client library, created to support programming scenarios for tabular models at compatibility level 1200 and higher.

### Analysis Management Objects (AMO)

Analysis Management Objects (AMO) is a library of programmatically accessed objects that enables an application to manage an Analysis Services instance.

### Trace events

Capture and analyze trace events generated by server instance. Trace events are grouped so that you can more easily find related trace events. Each trace event contains a set of data relevant to the event.

### Schema rowsets

Predefined tables that contain information about model database objects and server state, including schema, active sessions, connections, commands, and jobs executing on the server.

### Conceptual schema definition language (CSDL)

An XML-based language that describes entities, relationships, and functions in tabular models 1103 and lower compatibility levels and multidimensional models. Defined as part of the Entity Data Framework.

## Analysis Services Scripting Language (ASSL for XMLA)

Client applications can communicate with Analysis Services using XML commands and object descriptions. ASSL represents the object definition language portion of this XML dialect.

## ADOMD.NET

.NET Framework data provider designed to communicate with Analysis Services. ADOMD.NET uses the XMLA protocol to communicate with analytical data sources by using either TCP/IP or HTTP.

## XML for Analysis (XMLA)

A SOAP-based XML protocol for tabular and multidimensional data sources. Fundamentally, all client libraries supported by Analysis Services formulate requests and responses in XMLA.

## Data Analysis Expressions (DAX)

A library of functions and operators that can be combined to build formulas and expressions in Power BI Desktop, Azure Analysis Services, SQL Server Analysis Services, and Power Pivot in Excel.

## Multidimensional Expressions (MDX)

A library of functions and operators that can be combined to build formulas and expressions for SQL Server Analysis Services multidimensional models.

## Power Query M formula language

Used to query, filter and combine data from one or more supported data sources.

## PowerShell for Analysis Services

PowerShell cmdlets used to configure and administer an Analysis Services model database.

## PowerShell for Azure Analysis Services

PowerShell cmdlets used for resource management tasks like creating or deleting a server resource, suspending or resuming operations, or changing the service level (tier). Other tasks for managing databases like adding or removing role members, processing, or partitioning use cmdlets included in the SqlServer module.

# Analysis Services samples

Article • 12/09/2022

Applies to: SQL Server Analysis Services Azure Analysis Services Fabric/Power BI Premium

Use the information here to find sample databases and projects to help you learn about and test your Analysis Services solutions.

## Samples on GitHub

[Git repo for Analysis Services](#) includes code samples and community projects.

## Sample solutions and databases

While no longer officially supported, Adventure Works remains one of the most inclusive and robust sample datasets for learning about and testing Analysis Services. Analysis Services sample projects and databases, as well as examples in documentation, blog posts, and presentations use the Adventure Works sample data.

[Download Adventure Works sample projects and databases on GitHub](#) .

A new collection of sample data, Wide World Importers, was introduced for SQL Server 2016. You can use Wide World Importers sample data to learn about and test Analysis Services; however, no tutorials, examples, or documentation are provided. The Wide World Importers dataset and schema do not support many of the features in Analysis Services.
